Thanks to: The creators and archivers of ERA5

Diagnostics of ERA5 EDA control for surface pressure observations – 2010-2019

Eda Observations. CONV pSFC for ANN_2010010100-2019123112. Deep colours = 5% sig. (AR1)
Conventional surface observations (BRPA)

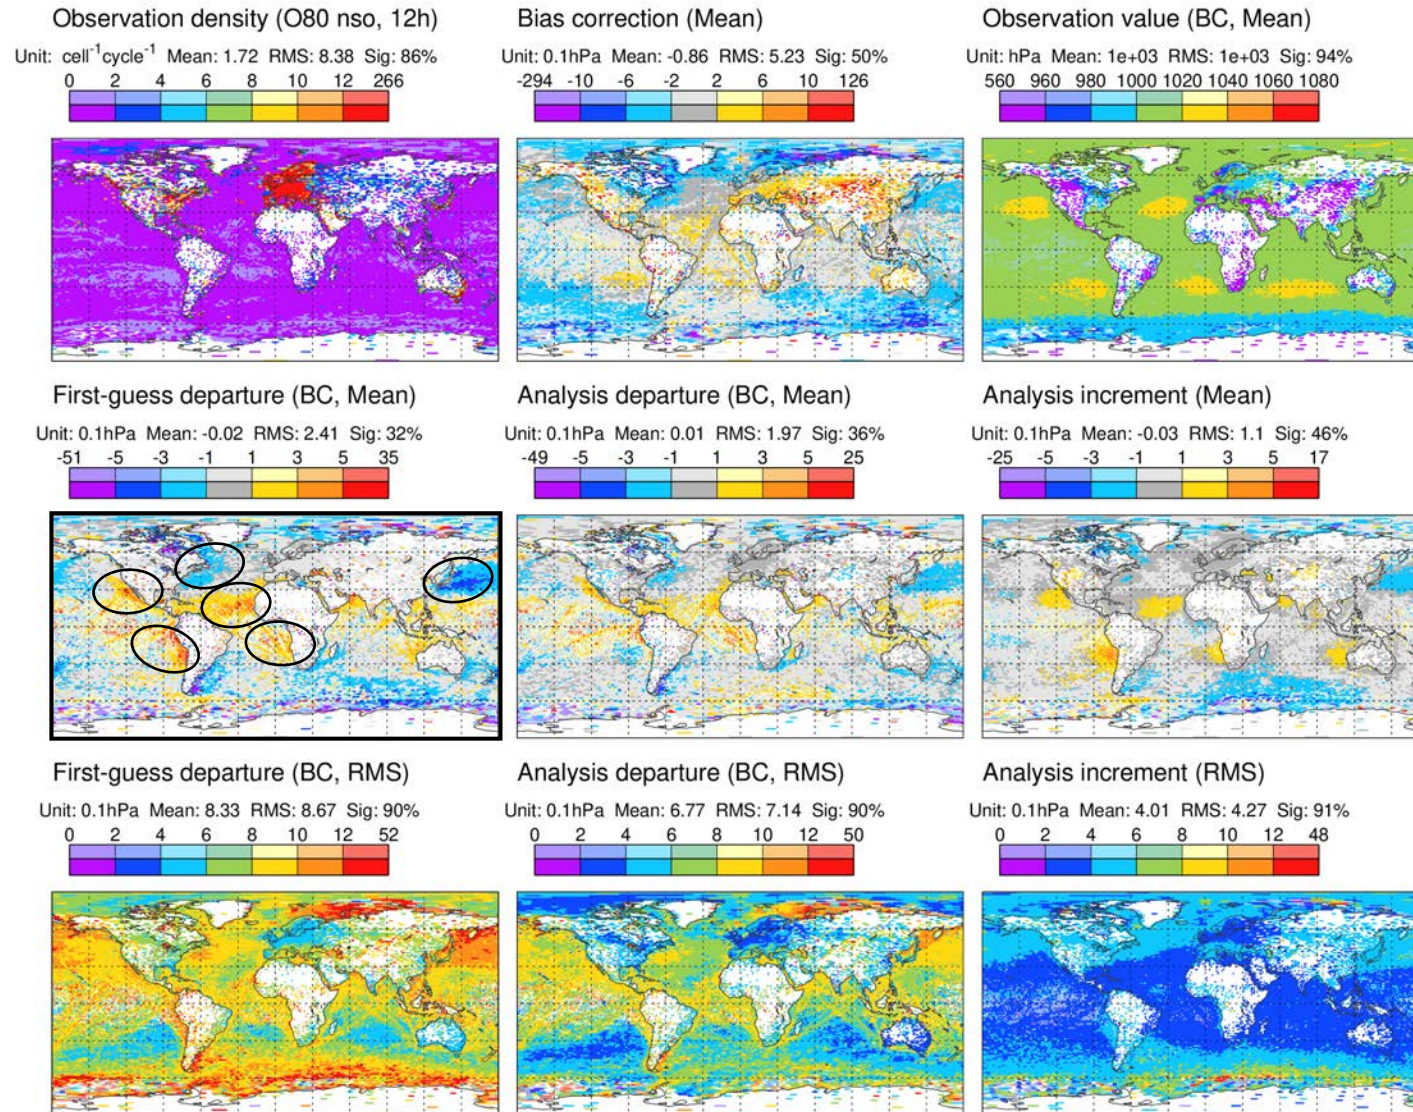

Observation: o
Background: b
Analysis: a
Variational bias correction: $o - o_{BC}$
First-guess departure: $o_{BC} - b$
Analysis departure: $o_{BC} - a$
Analysis increment: $a - b$

Decadal-means give coverage over most ocean regions

Diagnostics of ERA5 EDA control – 2000-2009

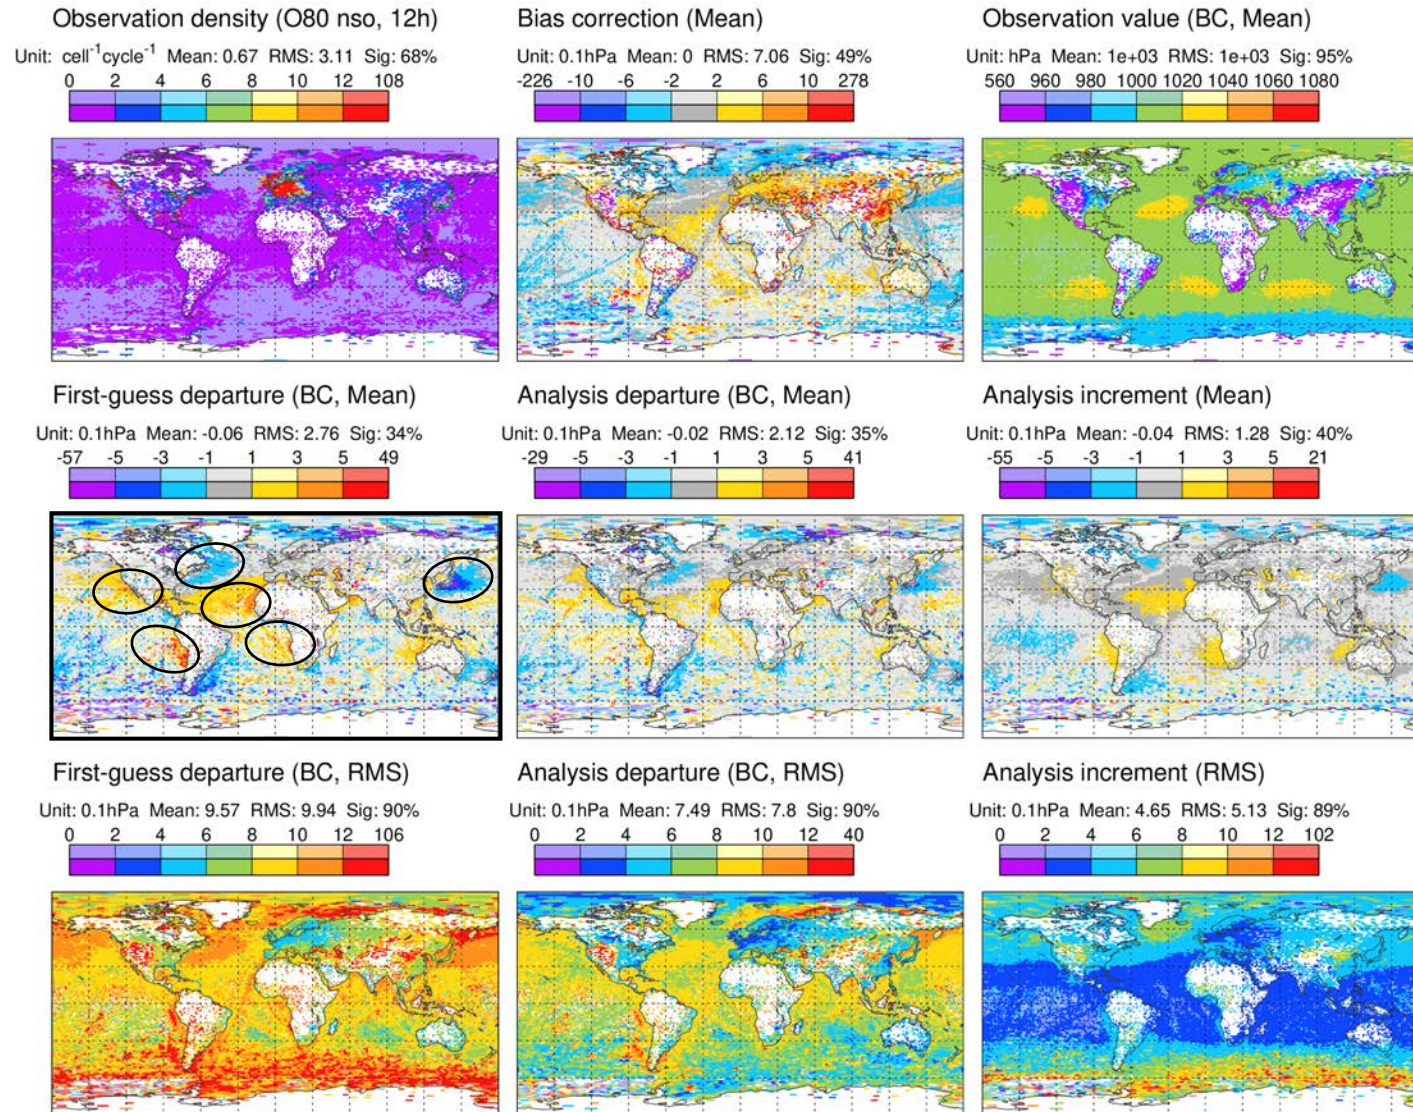

Eda Observations. CONV pSFC for ANN_2000010100-2009123112. Deep colours = 5% sig. (AR1)
Conventional surface observations (BRPA)

Departures and increments grow

Diagnostics of ERA5 EDA control – 1990-1999

Eda Observations. CONV pSFC for ANN_1990010100-1999123112. Deep colours = 5% sig. (AR1)
Conventional surface observations (BRPA)

Departures and increments continue to grow

Diagnostics of ERA5 EDA control – 1980-1989

Trend of increasing mean first-guess departures \Rightarrow trend in analysis bias \Rightarrow erroneous component to re-analysis trend

Sparser observations, more impact of model bias, need for model error representation

Bias correction strengthens (particularly over Atlantic) – it incorrectly absorbs some of the departures: $o-b = (o-o_{BC}) + (o_{BC}-b)$

Problem can be underestimated

Eda Observations. CONV pSFC for ANN_1980010100-1989123112. Deep colours = 5% sig. (AR1)
Conventional surface observations (BRPA)

Observation density (O80 nso, 12h)

Unit: $\text{cell}^{-1}\text{cycle}^{-1}$ Mean: 0.57 RMS: 1.57 Sig: 99%
0 2 4 6 8 10 12 34

Bias correction (Mean)

Unit: 0.1hPa Mean: 0.76 RMS: 8.08 Sig: 50%

Analysis increment (Mean)

Unit: 0.1hPa Mean: -0.03 RMS: 1.72 Sig: 43%
-87 -5 -3 -1 1 3 5 31

First-guess departure (BC, RMS)

Unit: 0.1hPa Mean: 11 RMS: 11.6 Sig: 92%
0 2 4 6 8 10 12 132

Analysis departure (BC, RMS)

Unit: 0.1hPa Mean: 8.37 RMS: 8.65 Sig: 93%
0 2 4 6 8 10 12 68

Analysis increment (RMS)

Unit: 0.1hPa Mean: 5.48 RMS: 6.51 Sig: 90%
0 2 4 6 8 10 12 132

The error-spread equation*:

$$\overrightarrow{(\bar{f} - T)^2} = \overrightarrow{(f - \bar{f})^2} + \vec{R}$$

EM Error² EnsVar Residual

f = ensemble member $\bar{\cdot}$ = ensemble mean (EM)
 T = truth $\overrightarrow{\cdot}$ = mean over forecasts

Reliability \Rightarrow Truth indistinguishable from forecast members \Rightarrow Residual $\rightarrow 0$

* Adjustment factor $\frac{m+1}{m-1}$ to EnsVar, which accounts for variance in \bar{f} (in Error² and EnsVar) due to finite ensemble size m , is not shown.

When observations of the truth have non-negligible errors, and we explicitly account for mean bias**:

$$\overrightarrow{\{(\bar{b} - o) - (\bar{b} - o)\}^2} = \overrightarrow{\{(b + \delta o) - \bar{b}\}^2} + \vec{R}$$

EM departure² ENS variance Residual
 (mean bias removed) (with observation error perturbations) (uncertainty deficit, variance in bias)

b = background member
 o = observation δo = obs perturbation to b

** Adjustment factors (which $\rightarrow 1$ for large m and large forecast sample size n) are not shown. In EDA $\overrightarrow{\delta o} \equiv 0$.

Rearranging gives us the EDA reliability budget***:

$$\overrightarrow{(\bar{b} - o)^2} = \overrightarrow{(b - \bar{b})^2} + \overrightarrow{\delta o^2} + \overrightarrow{(\bar{b} - o)^2} + \vec{R}$$

EM Depar² EnsVar ObsUnc² Bias² Residual

*** Adjustment factors not shown. Note that $\overrightarrow{2\delta o(b - \bar{b})}$ subsumed into Residual, but $\rightarrow 0$ in any case.

Reliability \Rightarrow Bias $\rightarrow 0$ and Residual $\rightarrow 0$

Reliability budget of ERA5 EDA for surface pressure observations – 2010-2019

Eda Observations. CONV pSFC for ANN_2010010100-2019123112. Deep colours = 5% sig. (AR1)
Conventional surface observations (BRP^A)

Residual

Observation density (O80 nso, 12h)

Trend of increasing under-spread – Due to increased influence of prescribed SST or under-estimation of early satellite errors?

Going back in time:

Sparser observations leave re-analysis at the mercy of model bias

- Tackle with “Weak Constraint” (model error term) in assimilation
- To prevent climate projection biases, improve underlying model
- Attention to variational observation bias correction too

Larger uncertainty (but not large enough)

- False impression of accuracy of product
- Unreliable initialisation of re-forecasts
- Due to under-estimation of uncertainties in SST or early satellite observations?

Operational diagnostics applied to ERA5 are available at:

<https://apps.ecmwf.int/webapps/intraplots/packages/diagnostics/>

(Move of computing facilities to Bologna so can be a little intermittent)
