

Estimating the risk of collapse of the AMOC

Peter Challenor and the RAPIT Team

RAPIT

- Consortium of NOC, Universities of Reading, Durham and Oxford, Imperial College, London School of Economics, the British Antarctic Survey and the UK Met Office
- Set up at a NERC 'Sandpit'

- What is the risk that the AMOC will shut down (or slow)?
- No philosophy talk

Models

- Uncertainty in climate models
 - Input uncertainty (initial conditions, parameters, forcings)
 - Structural uncertainty

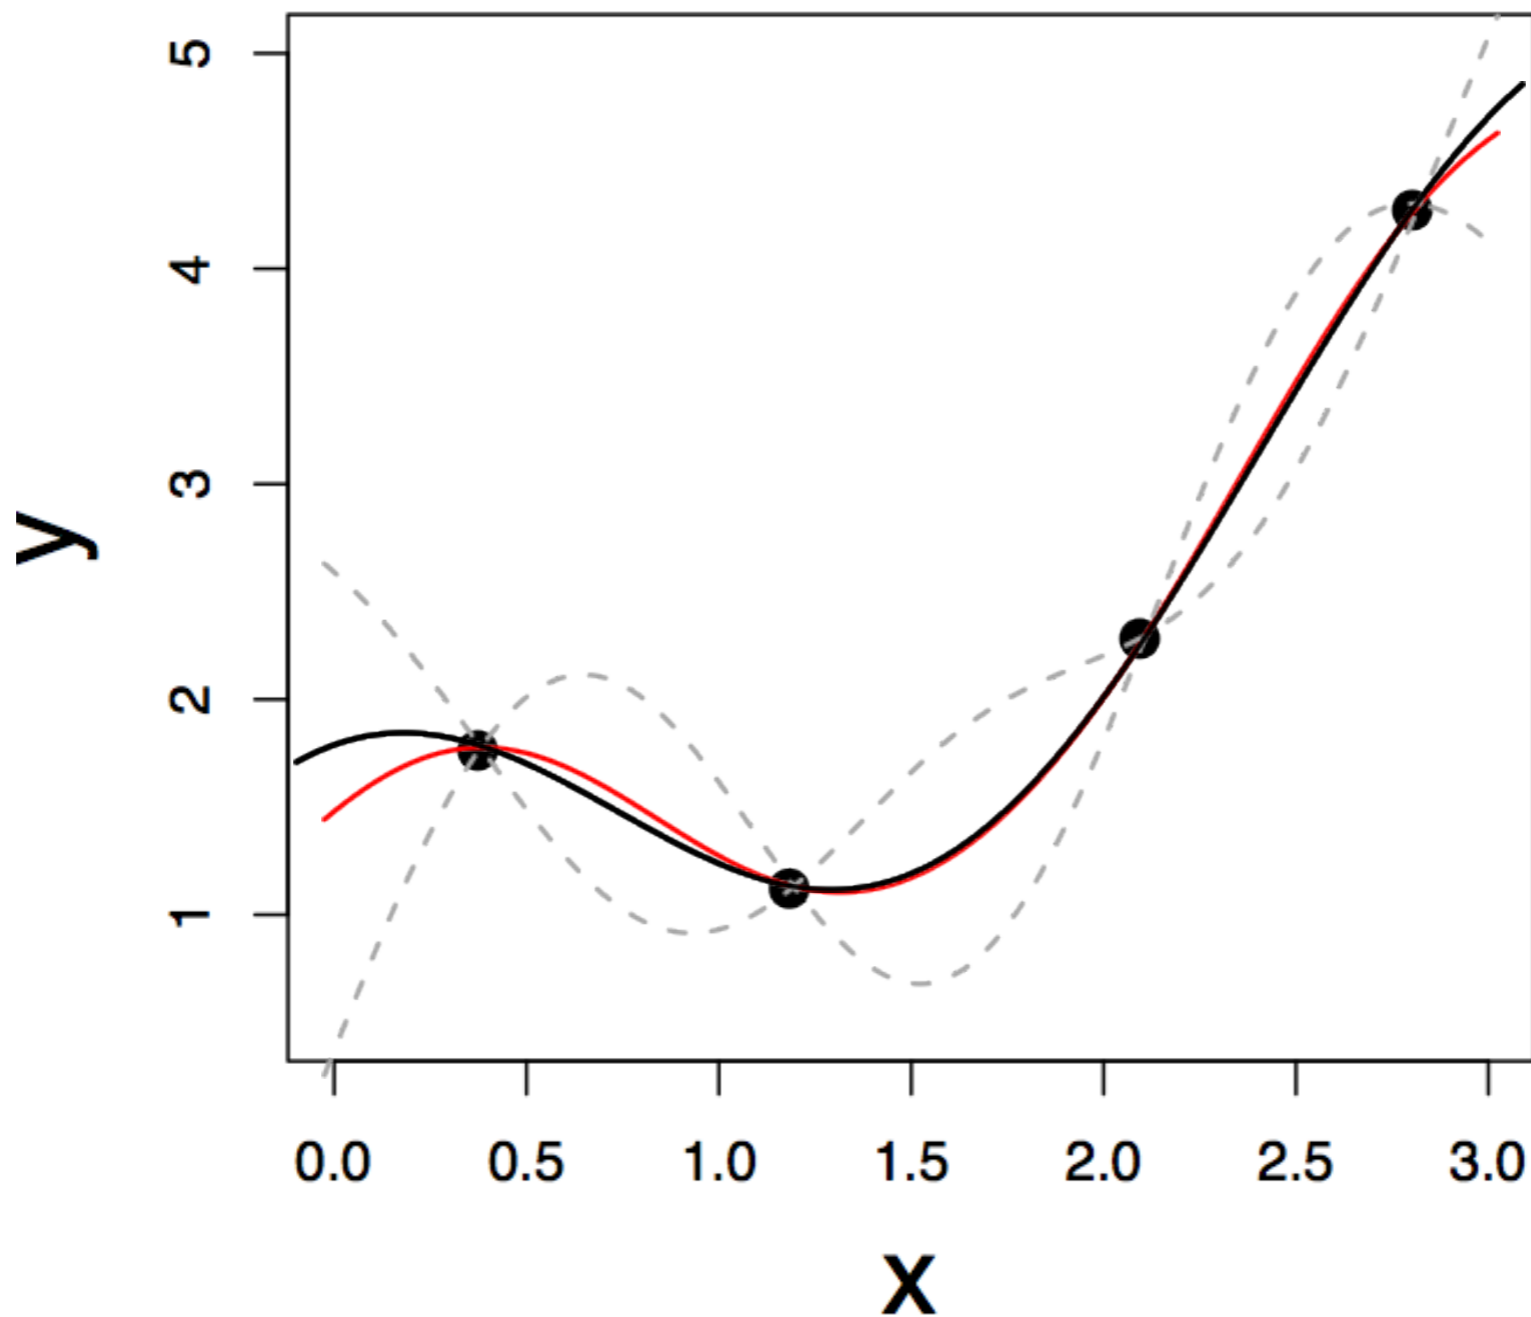

Tuning and Discrepancy

- Input uncertainty
 - Tuning, calibration
- Structural uncertainty, error
 - Model discrepancy

Emulators

- Climate models are expensive to run
- An emulator is a statistical model of the climate model

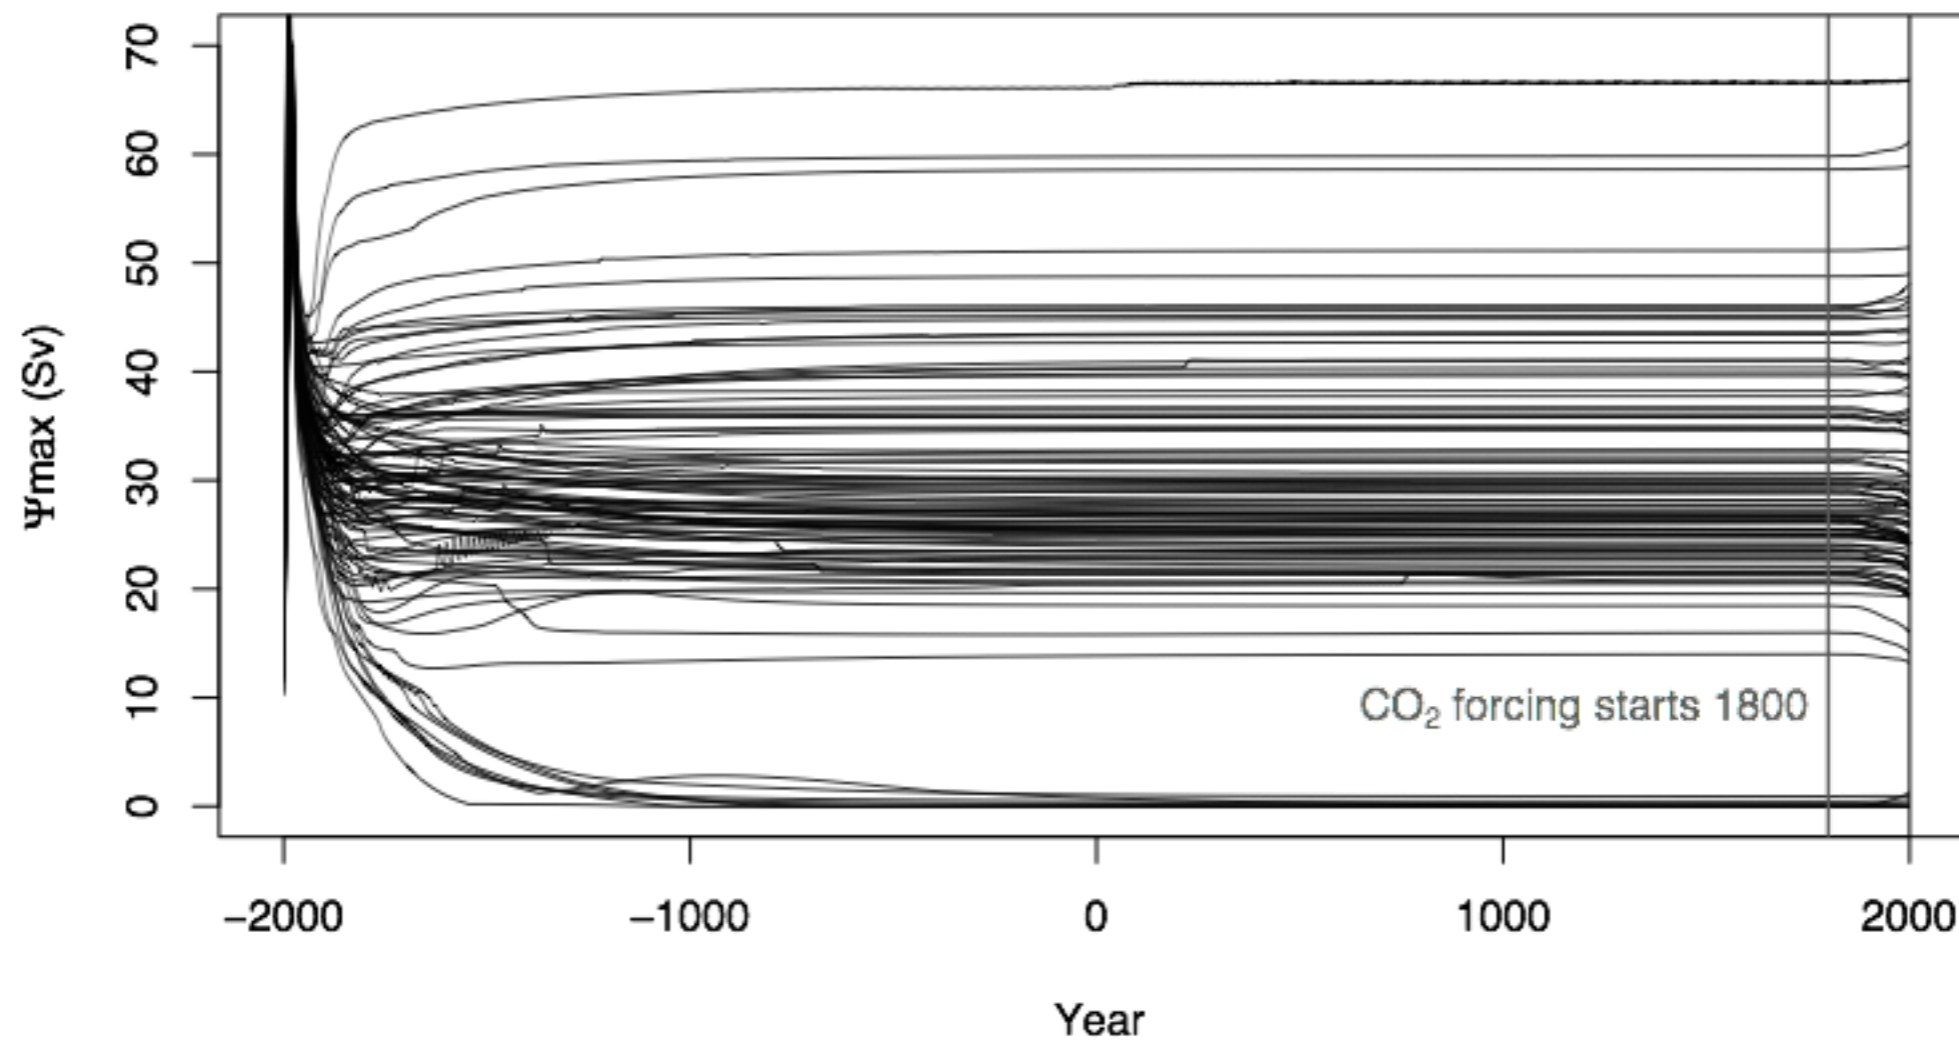

An Example

Procedure

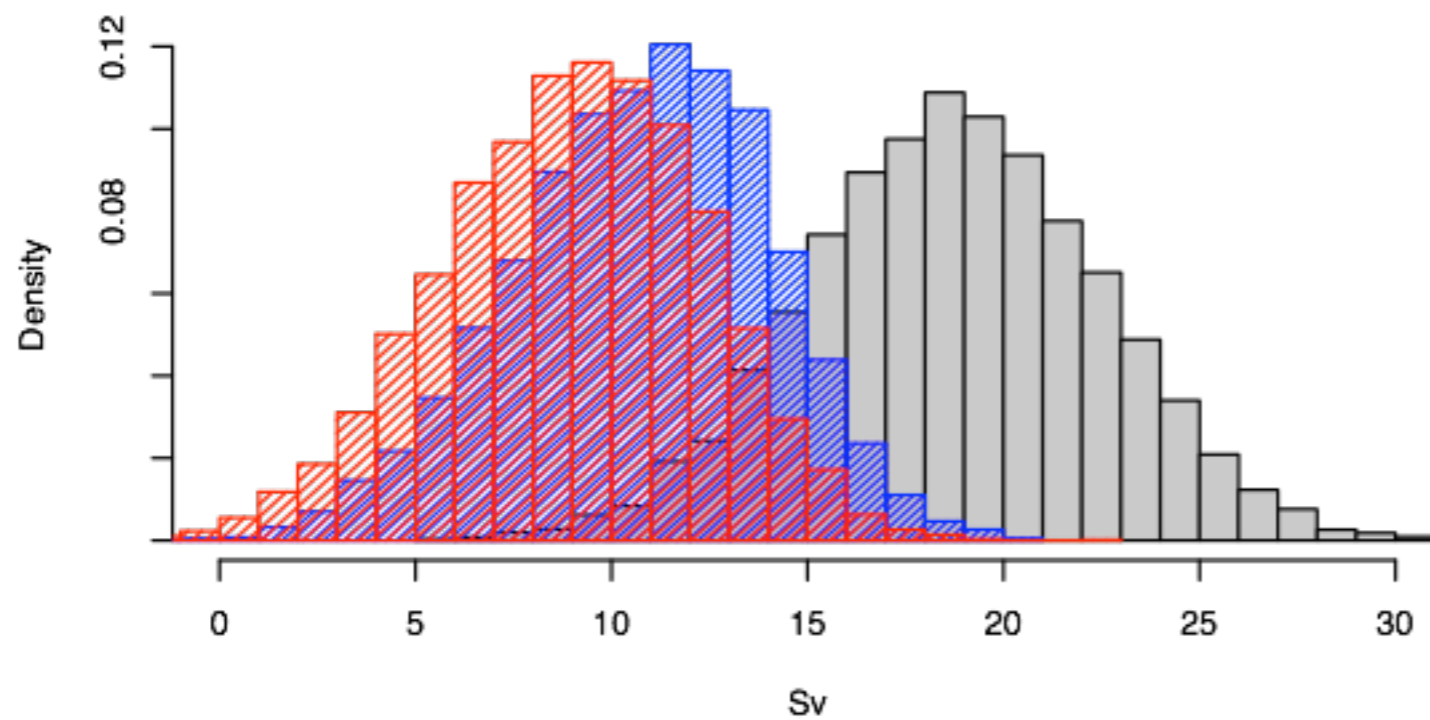

- Run an ensemble of climate models in a designed experiment
- Build emulator
- Validate
- Use emulator inferences about the model and via model discrepancy real climate

GENIE Training Set

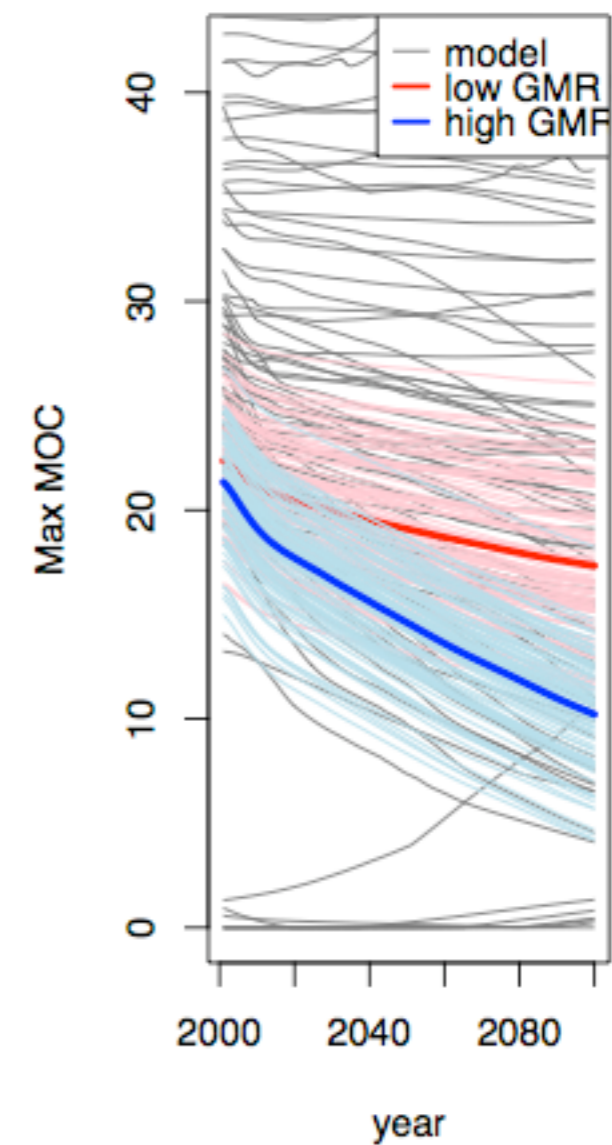

MOC at 2000 (grey) Vs A1FI (red) Vs B2 (blue)

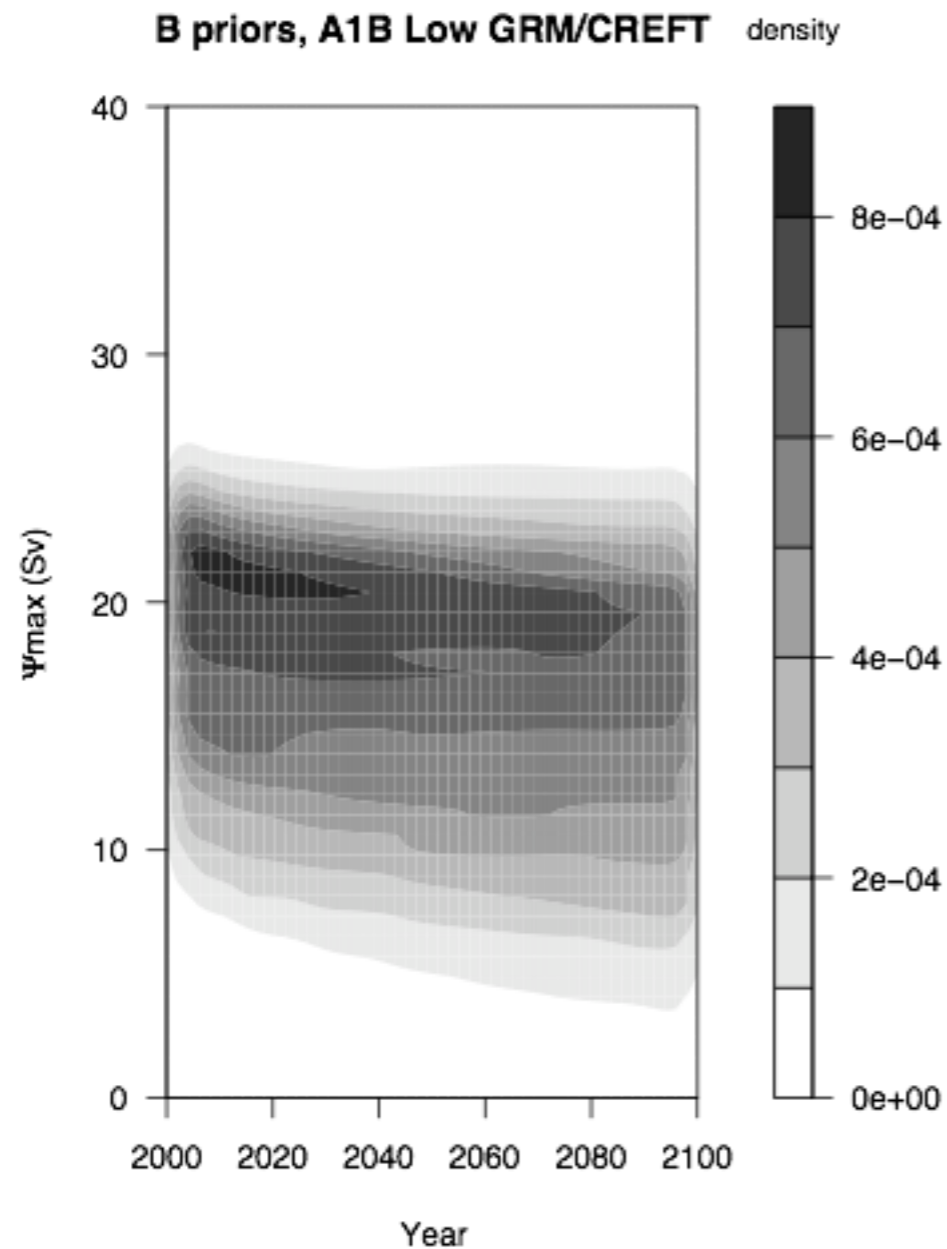

Challenor et al 2010

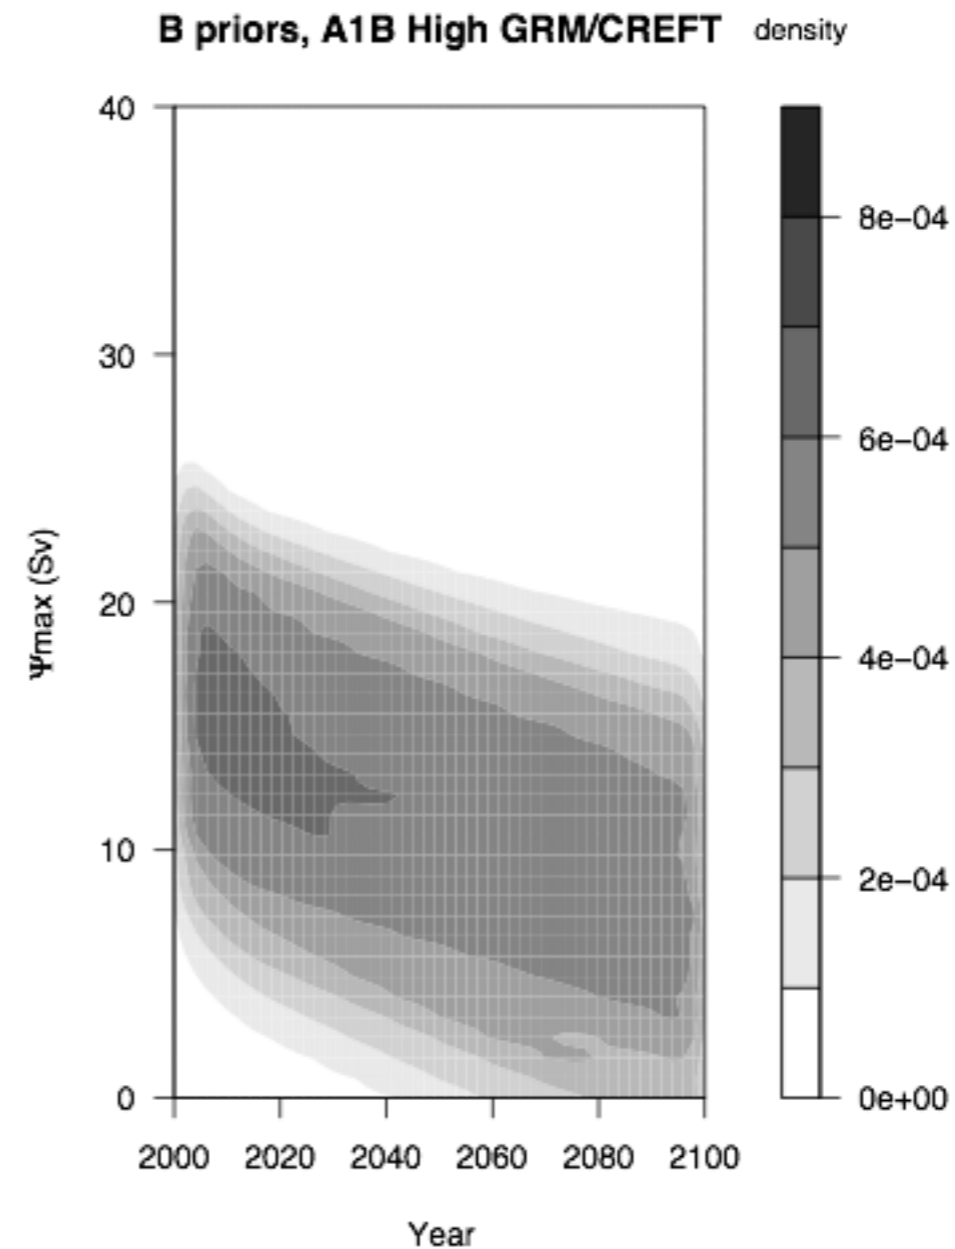

MOC uncertainty analysis

Estimated Decline in the Strength of the MOC from GENIE

Low Greenland
melting rate

High Greenland
melting rate

Genie Results

Scenario	Low Melt Rate for Greenland	High Melt Rate for Greenland
A1B	0.09	0.35
A2	0.10	0.33
B1	0.10	0.30

RAPIT Experiment

- Use HADCM3 rather than Genie
- Run large ensemble on *climateprediction.net*
- ‘Calibrate’ HADCM3
- Relate the model to reality (discrepancy)
- Estimate the risk of AMOC collapse in the real, not model, world

climateprediction.net

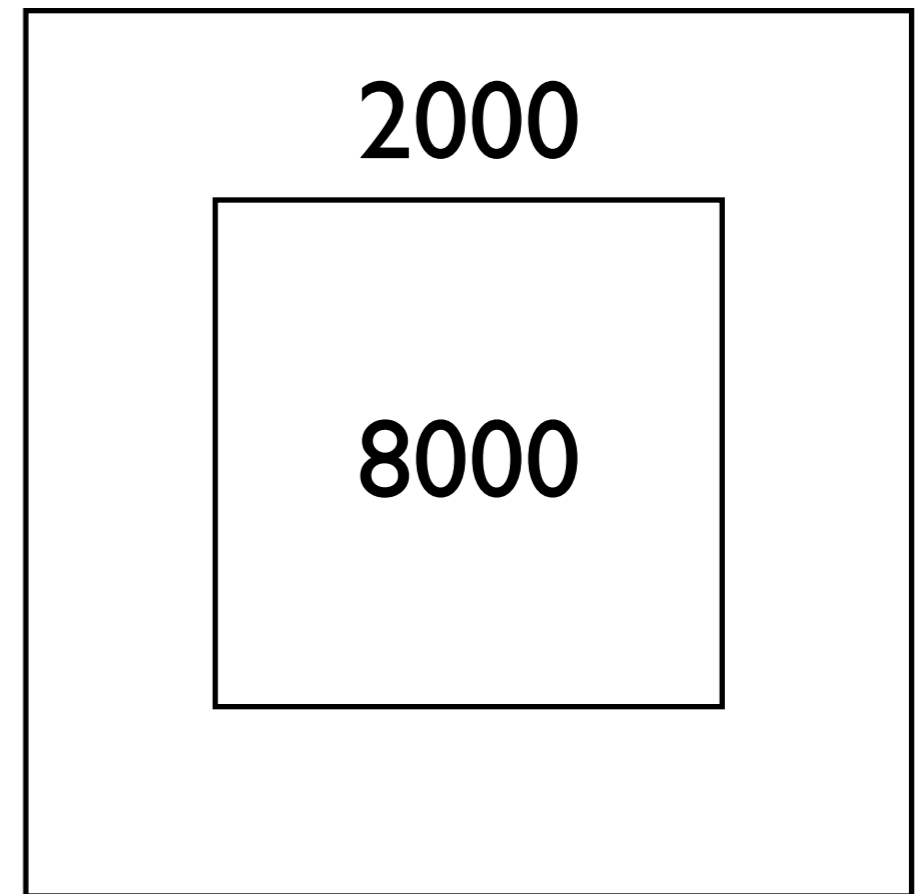

- Runs climate models (32-bit HADCM3) on home PC's
- Based at Oxford University
- Enables us to run large (c10000) ensembles
- But slow and not reliable
- Run 40 year pieces
- Don't get all the output back (bandwidth)

The RAPIT ensemble

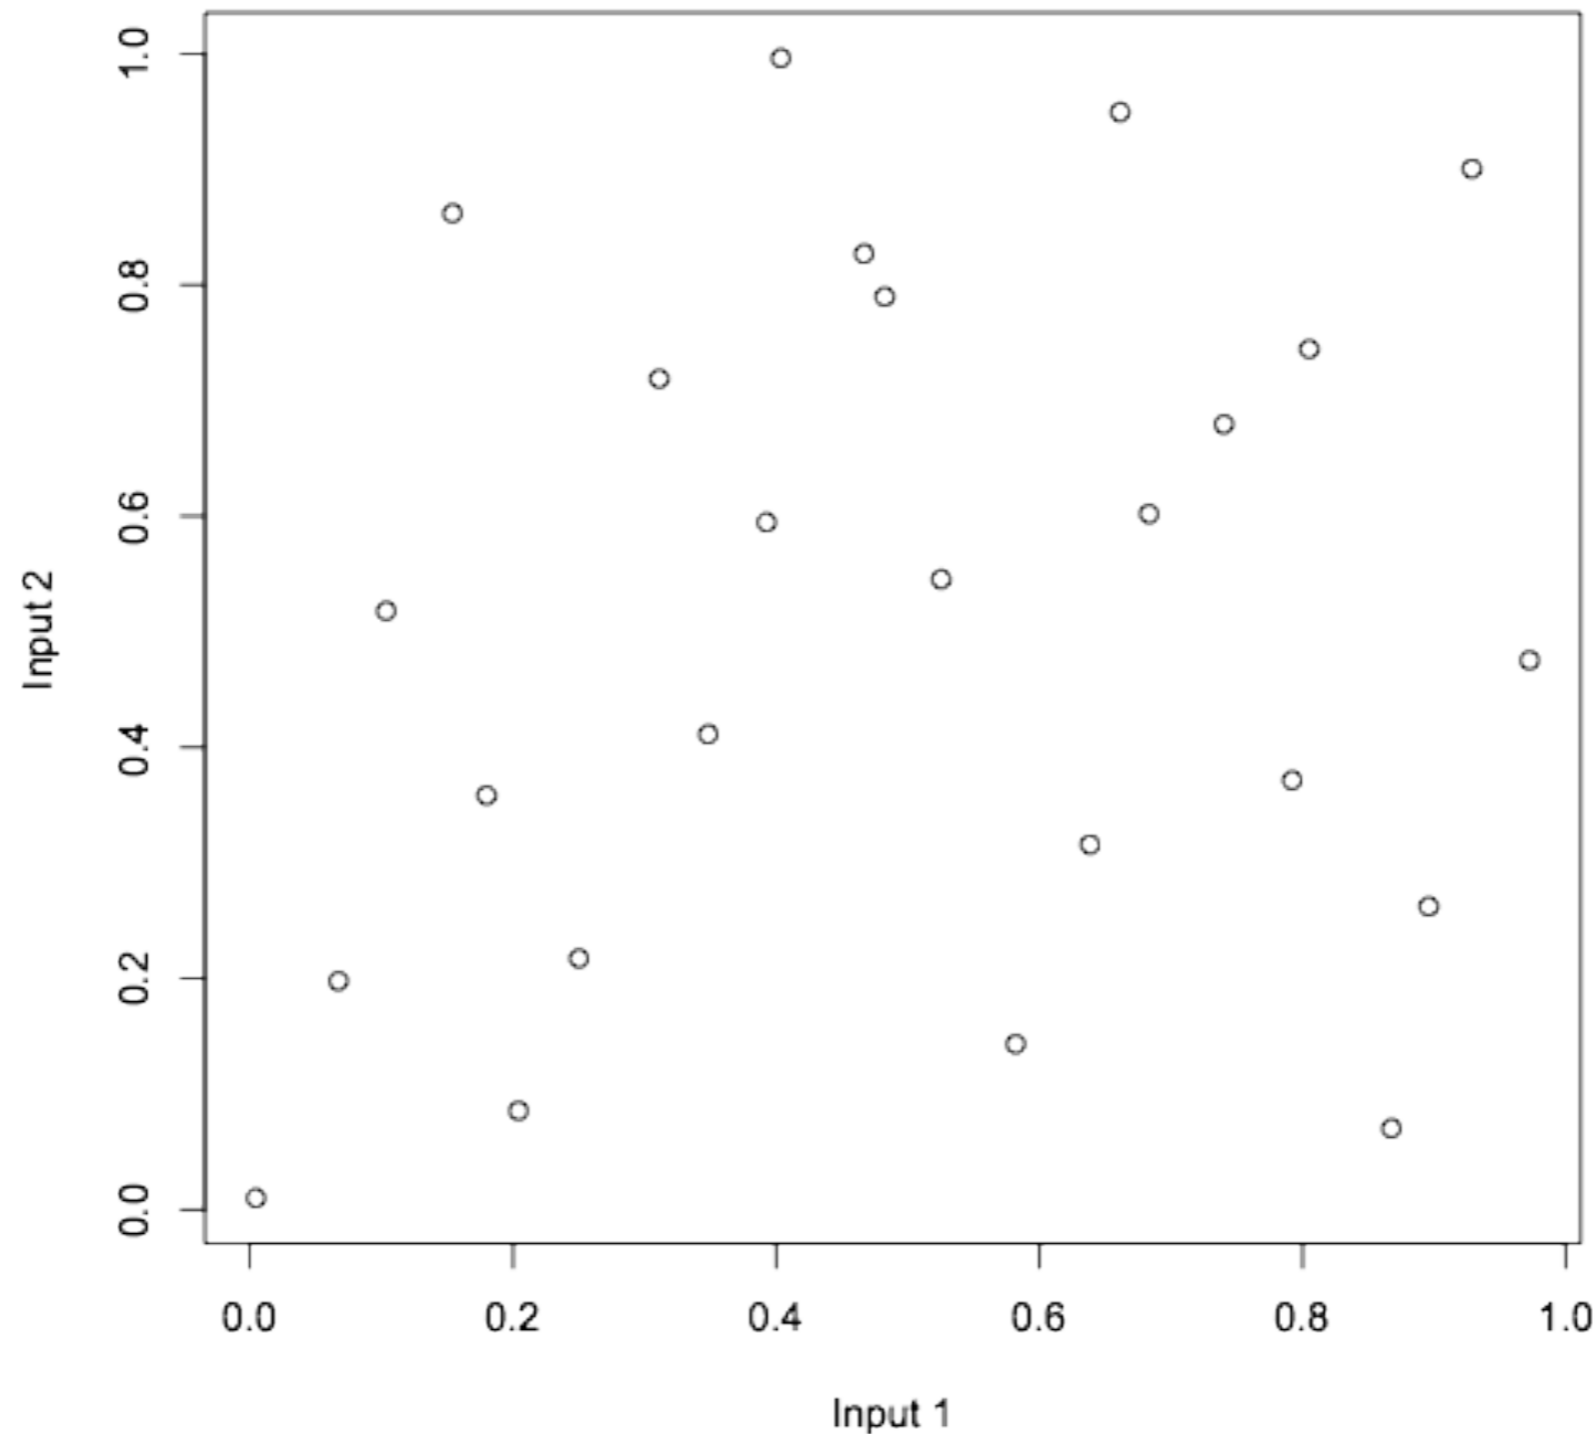

- Run in 40 year lengths
- All runs duplicated
- Control runs - just keep running
- CO₂ forcing - spread of CO₂ increase 0-4%
 - 40 year control; 10 year control 30 year increase; 40 year increase
- 20th Century
 - 120 year control + 20th century forcing
- 21st Century
 - 20th century + CO₂

The RAPIT Design

- Nested nearly-orthogonal Latin Hypercubes
- Central one based on Met Office ranges for parameters (8000)
- Outer one with extended ranges (2000)

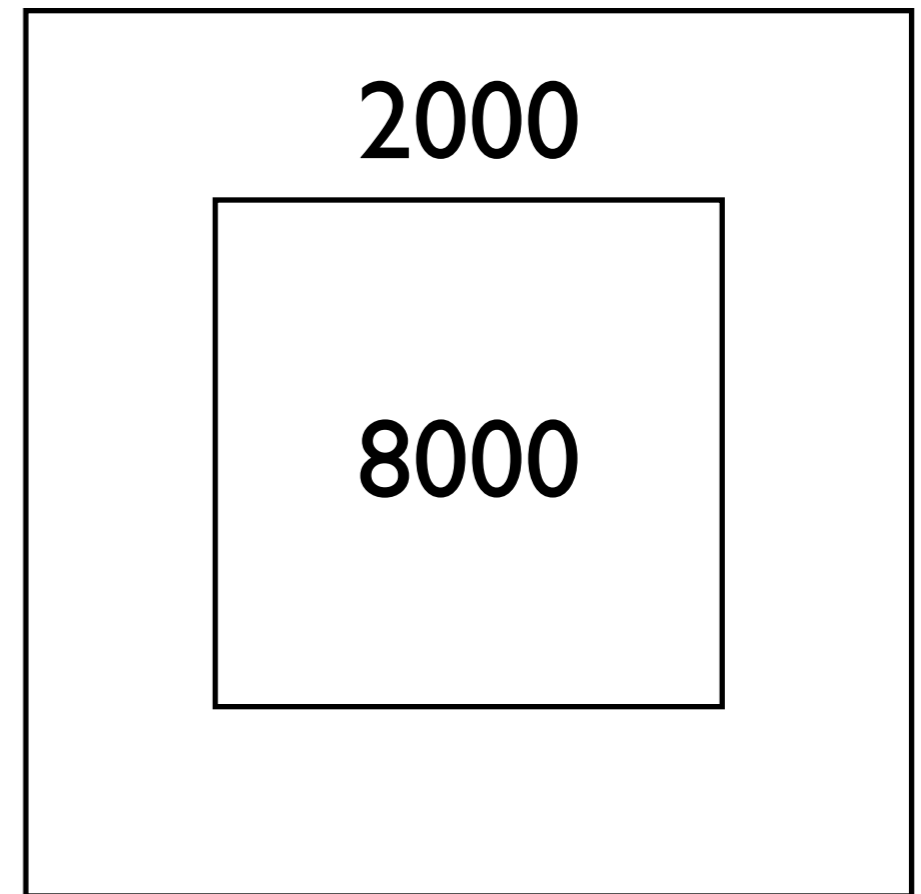

A Latin Hypercube

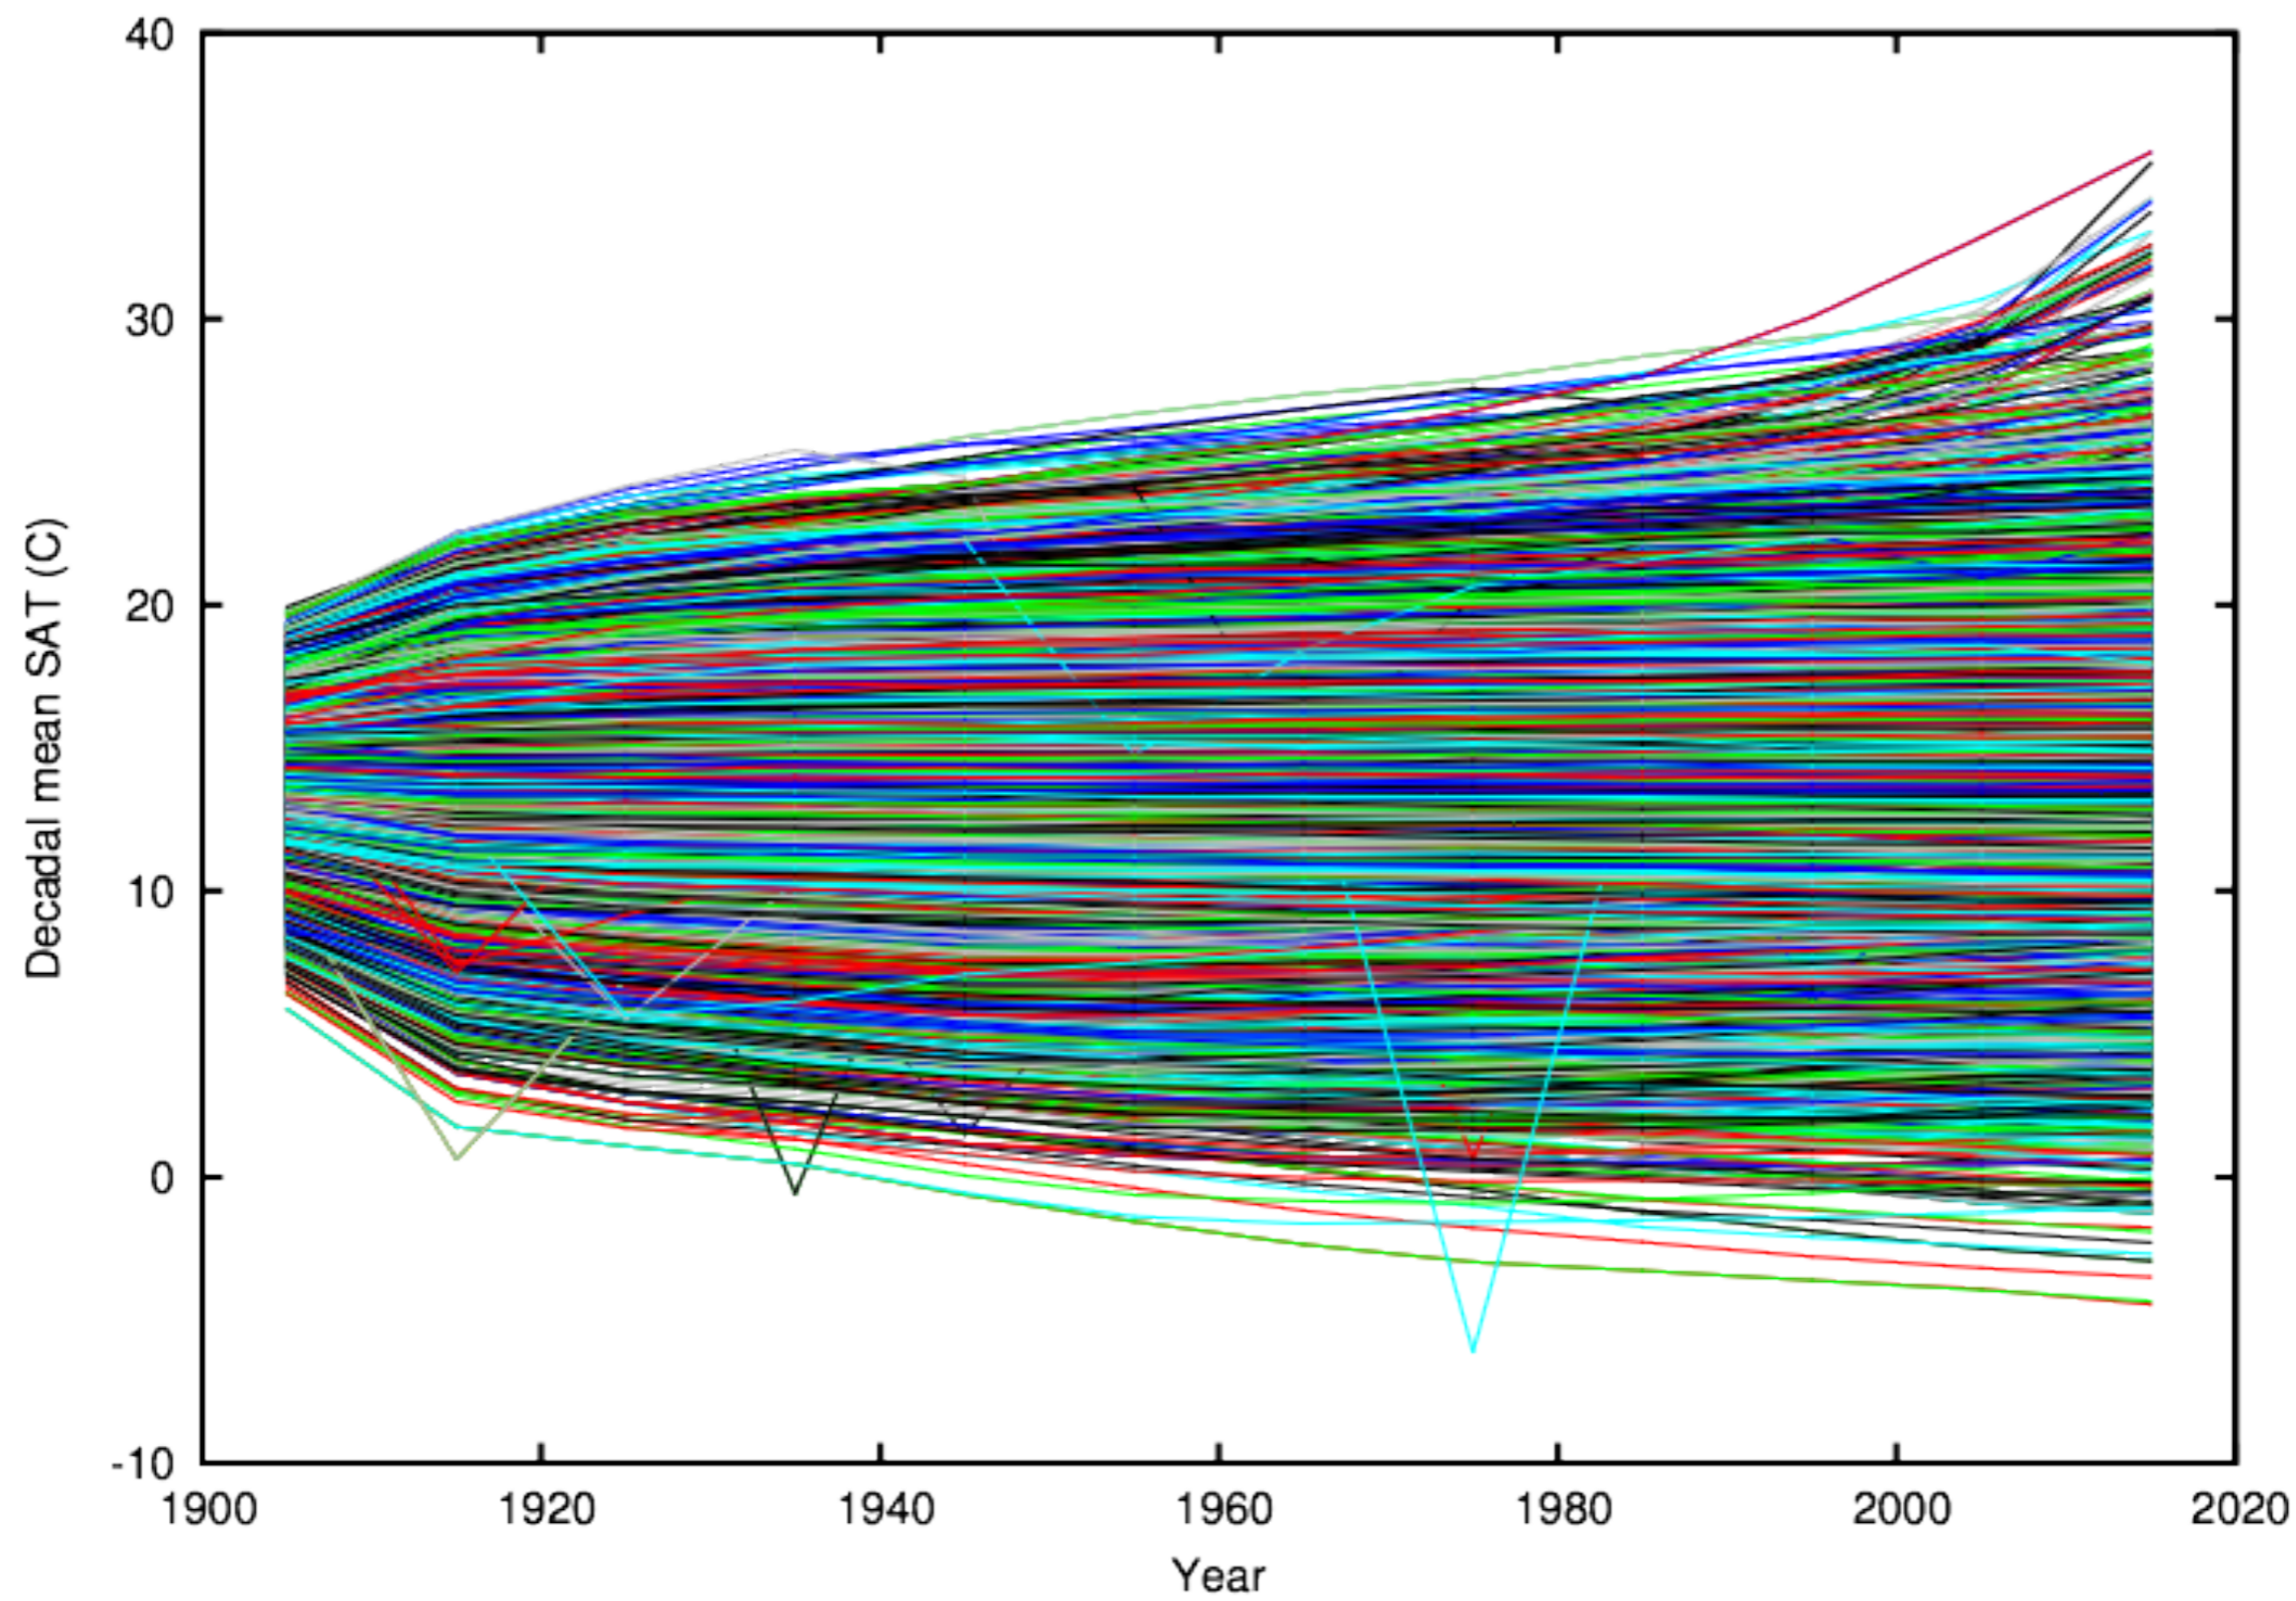

The RAPIT Design

- Nested nearly-orthogonal Latin Hypercubes
- Central one based on Met Office ranges for parameters (8000)
- Outer one with extended ranges (2000)

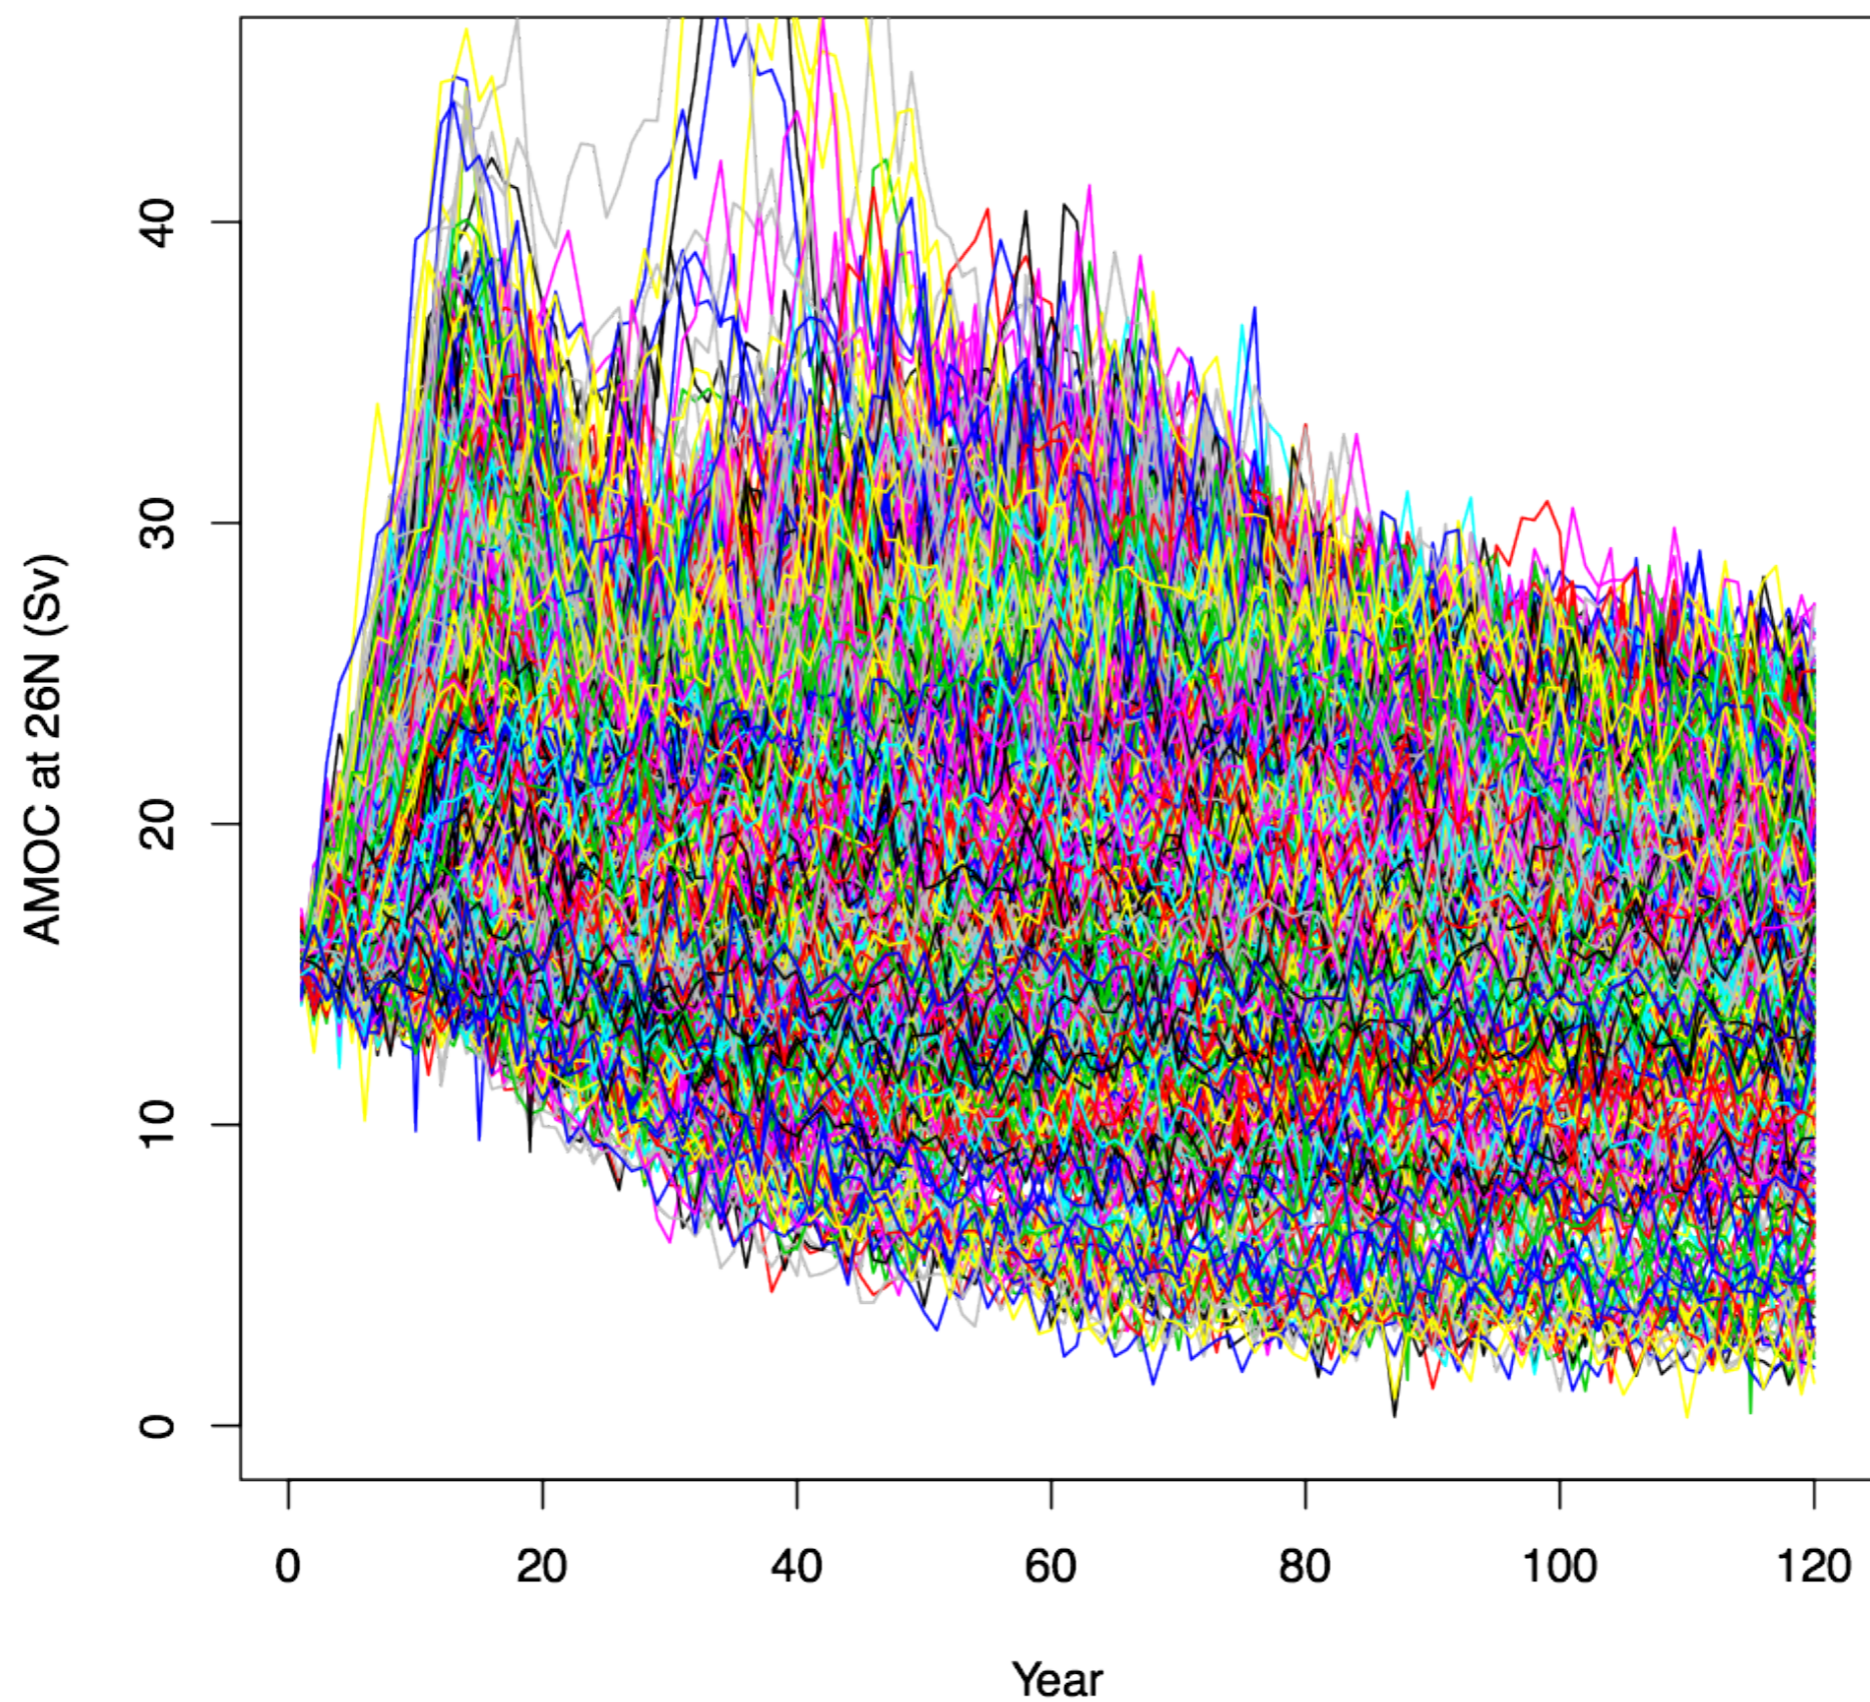

Important Point

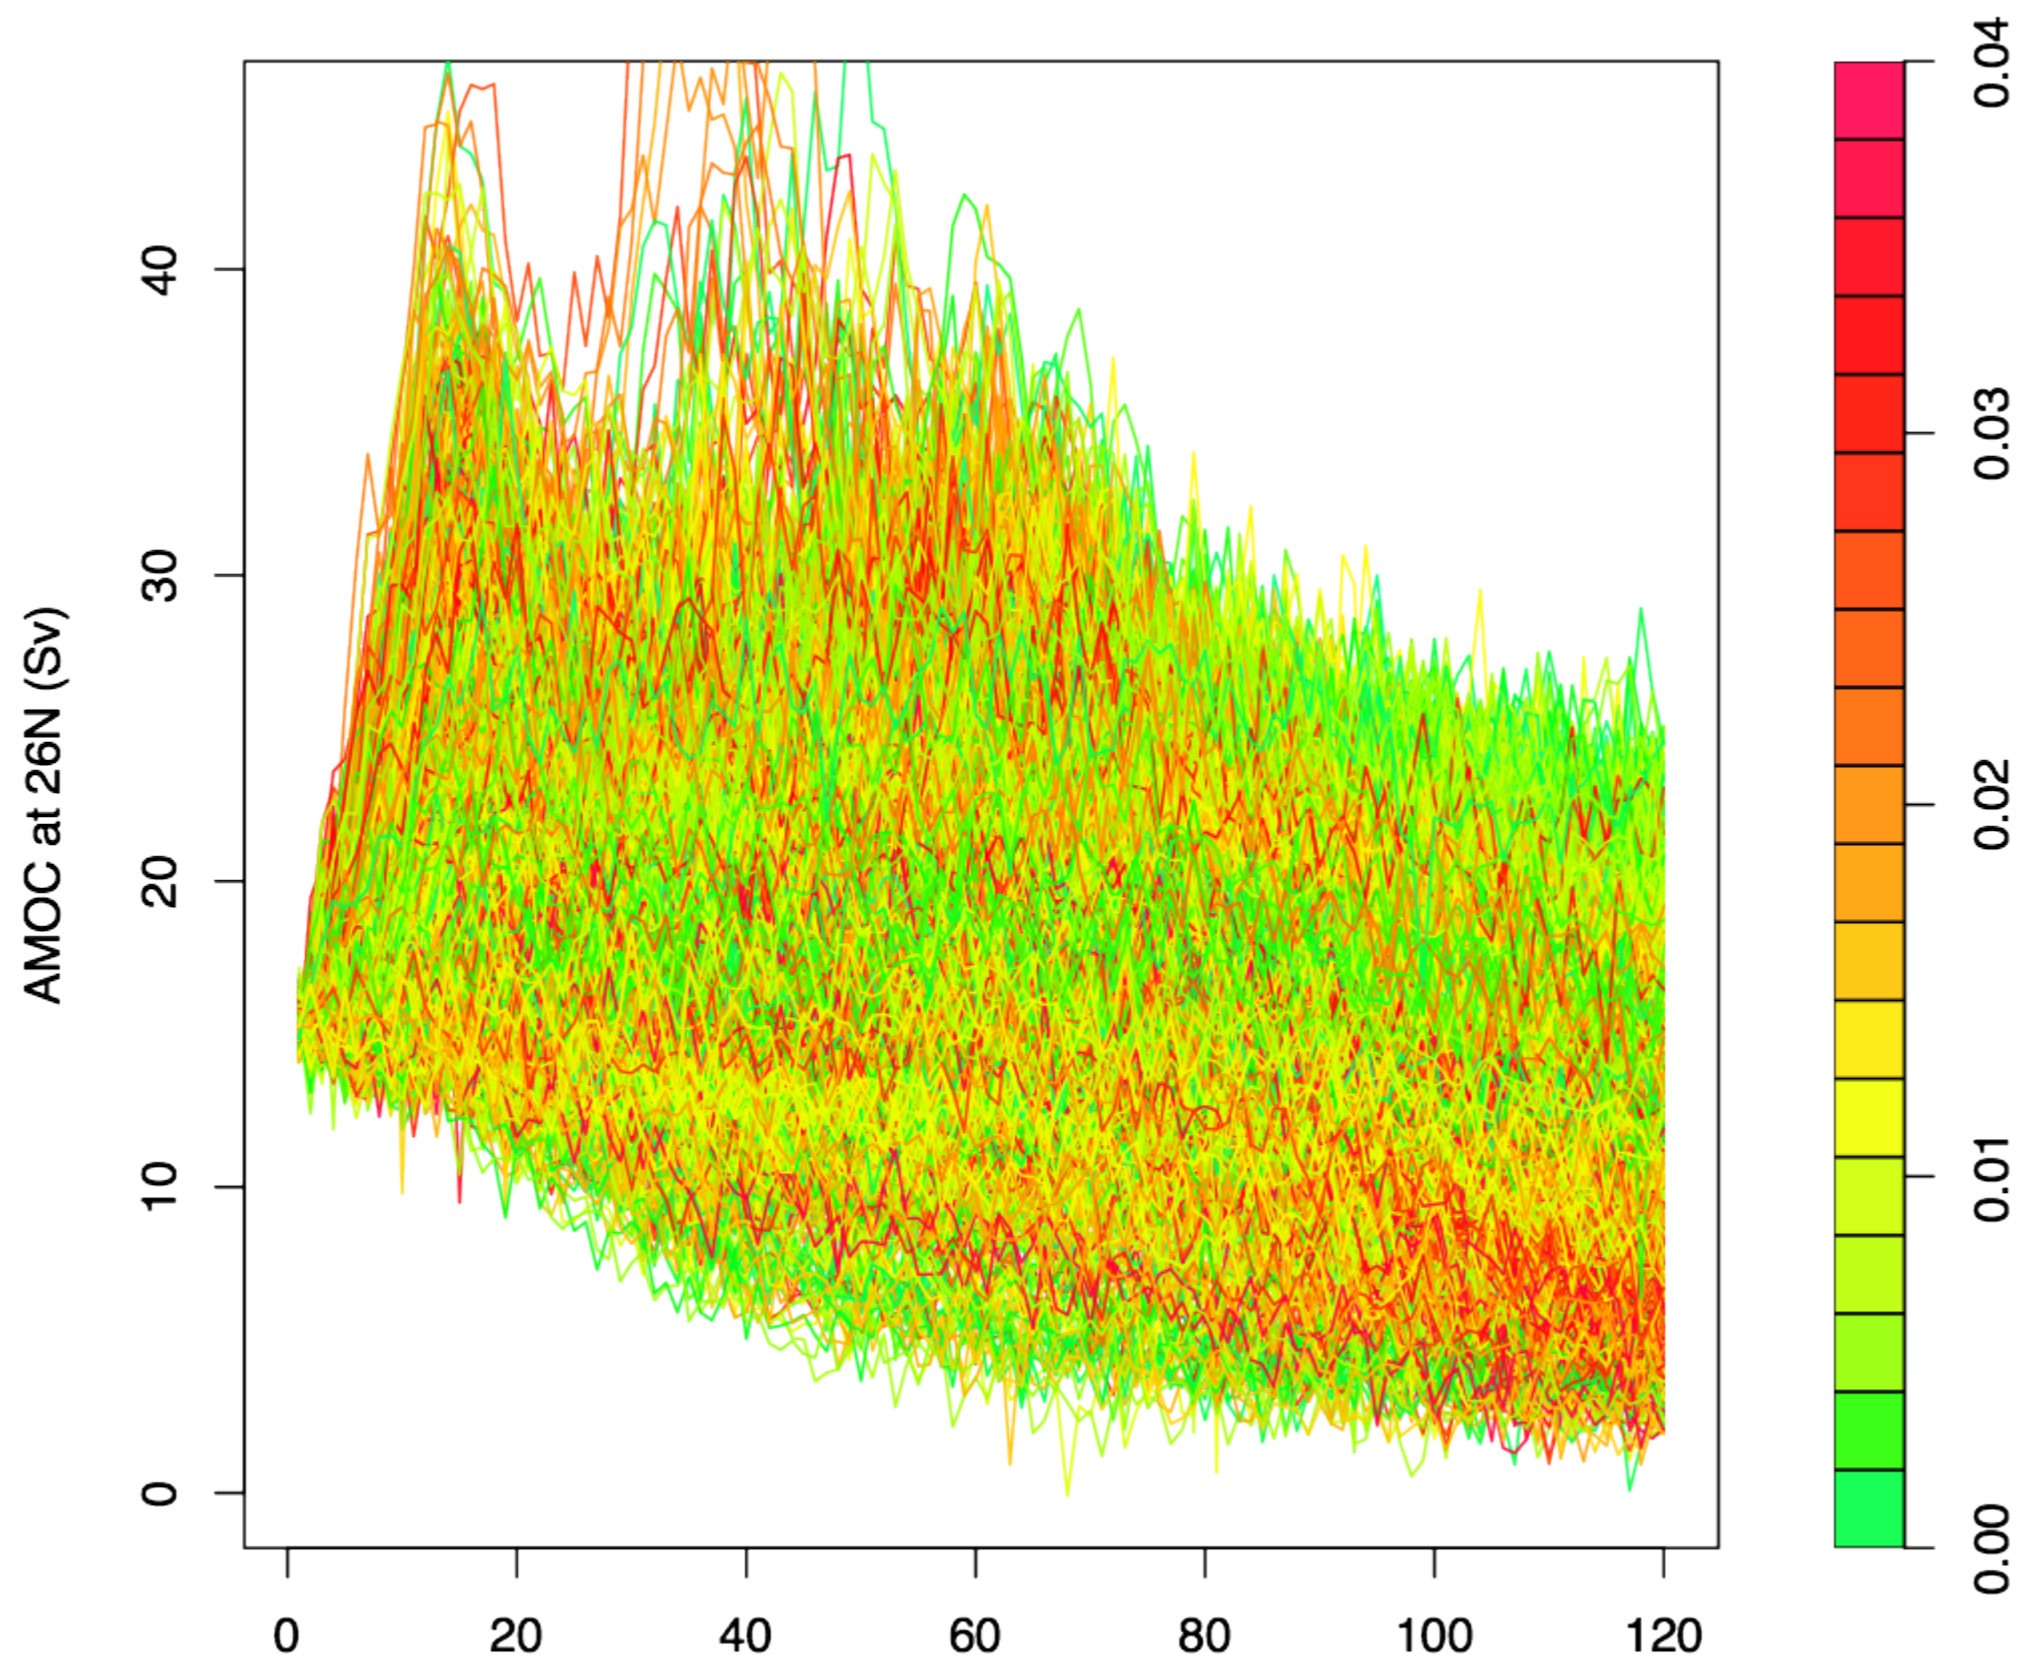

- We run all simulations to the end regardless of how 'bad' the climate they give is

Control AMOC in the RAPIT ensemble

Transient AMOC in the RAPIT ensemble

History Matching

- Rather than try to find the best set of parameters
- Find which regions of input space which implausible

Implausibility

- Define a measure of implausibility (I_{mp})

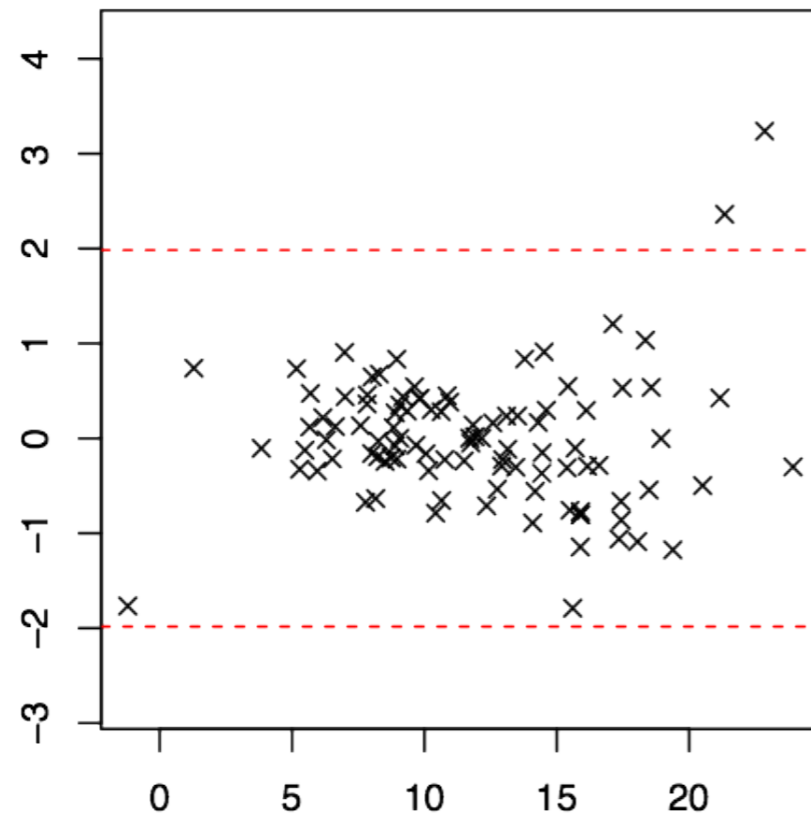

$$I_{mp}^2 = \frac{(x_{obs} - x_{emul})^2}{\sigma_{emul}^2 + \sigma_{obs}^2 + \sigma_{discrep}^2}$$

- If the implausibility is greater than ± 3 those values of the inputs are deemed implausible
- Because this is a function of the emulator not the original simulator runs we calculate it everywhere in input space

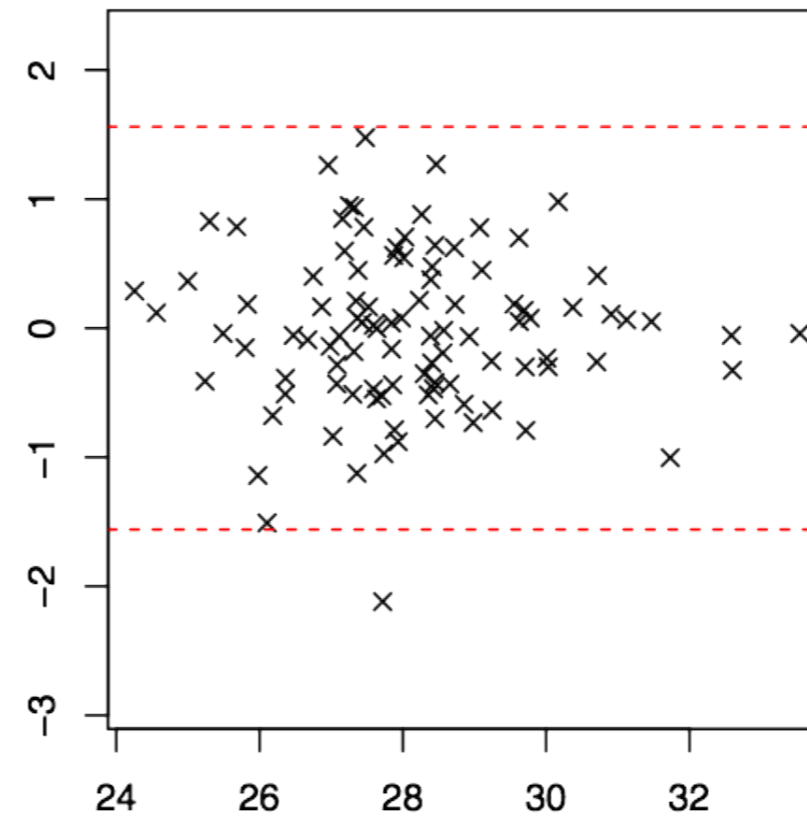

History Matching in RAPIT

- Only pre-industrial runs so far
- Estimates of pre-industrial
 - SAT
 - N. Hemisphere-SATgradient
 - Seasonal cycle in SAT
 - Global precipitation

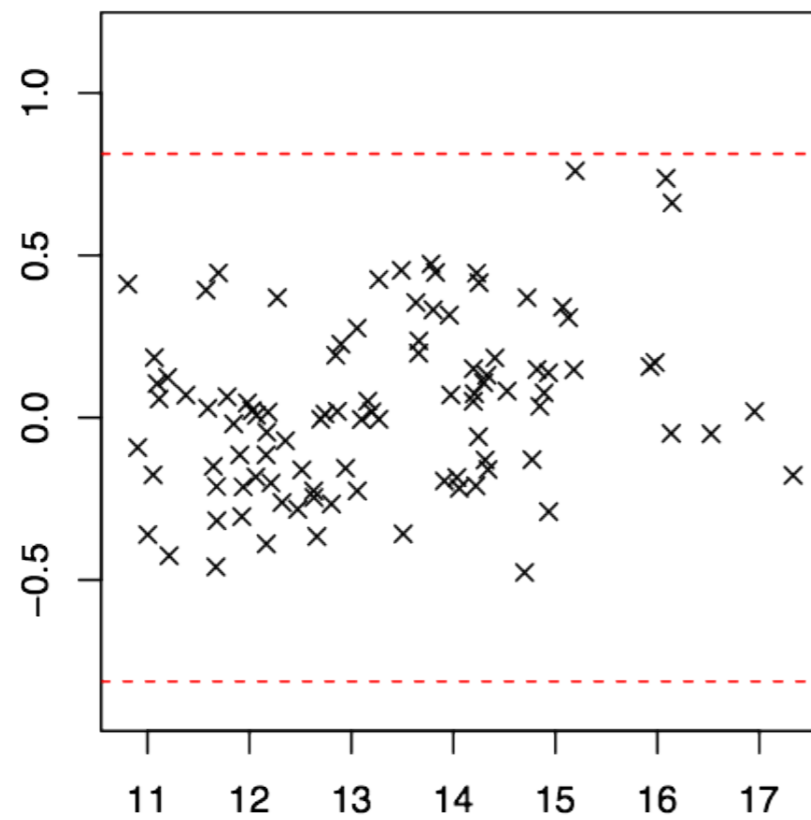

SAT Validation

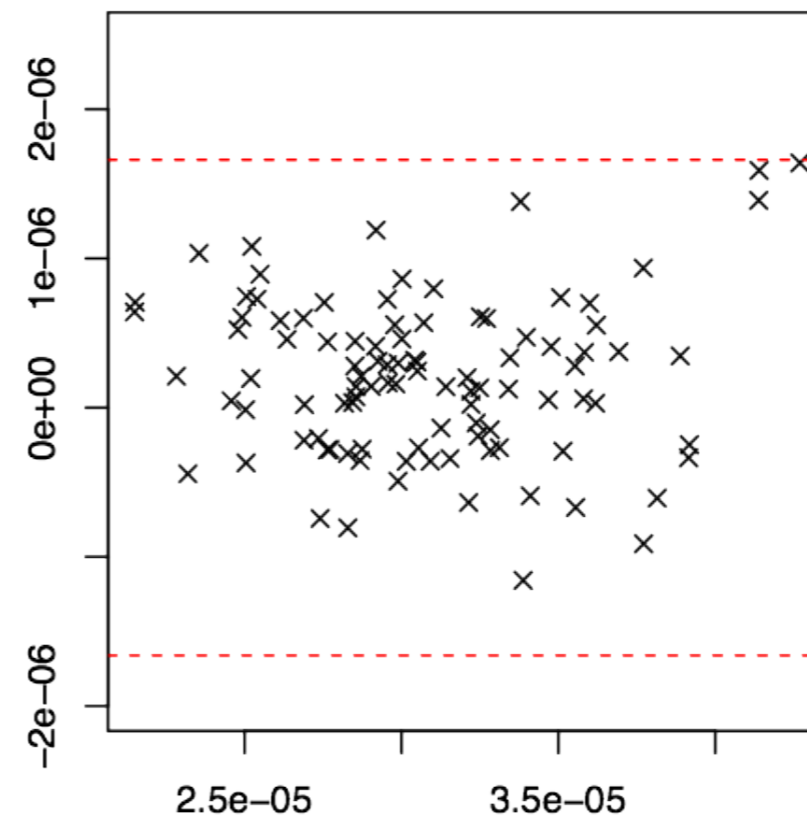

SATGRAD Validation

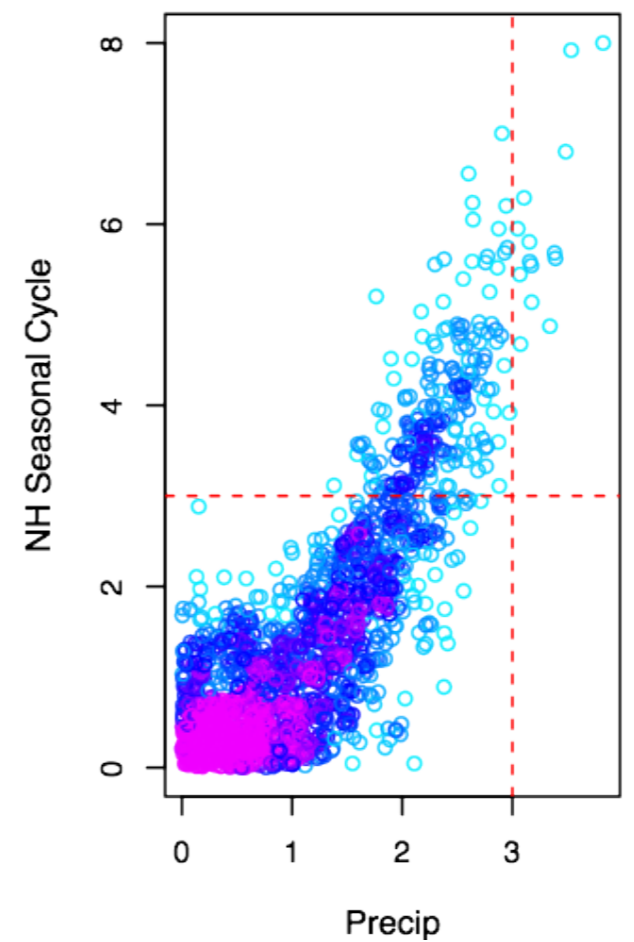

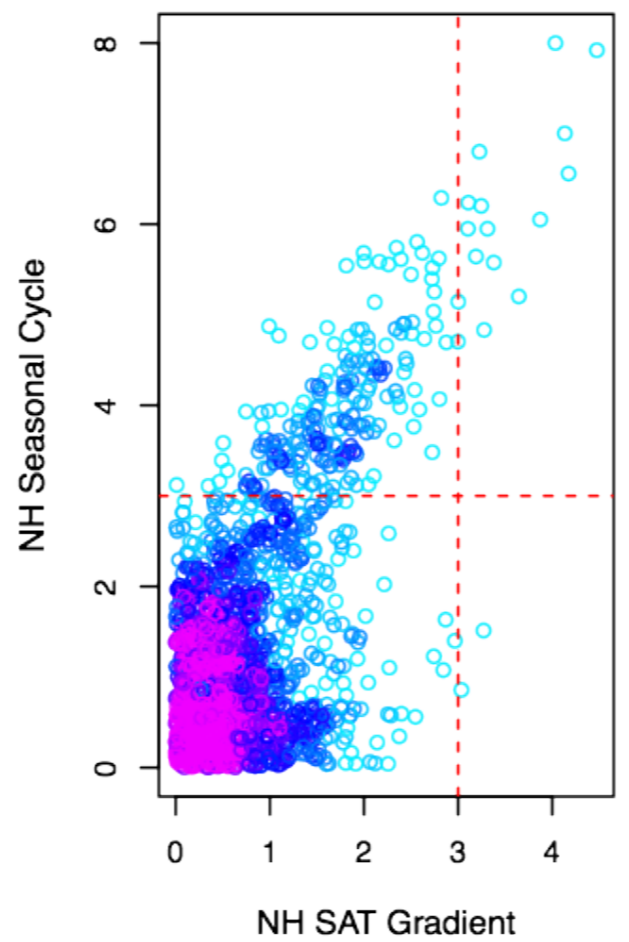

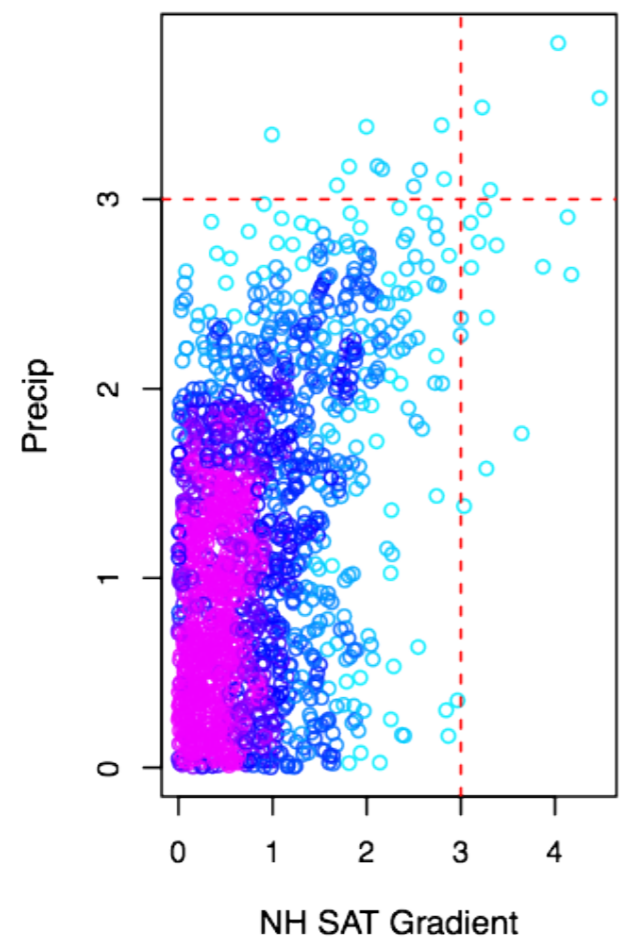

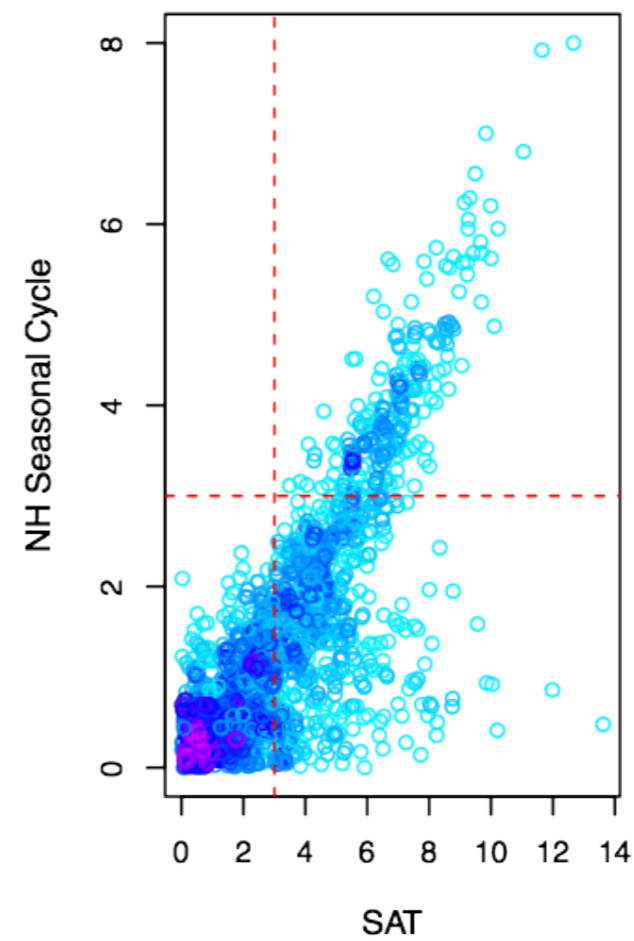

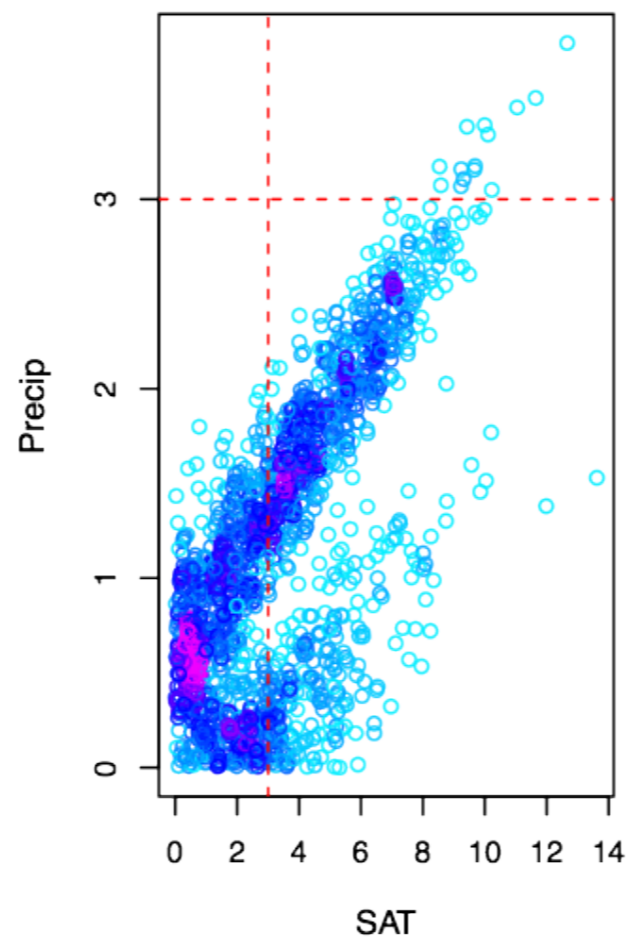

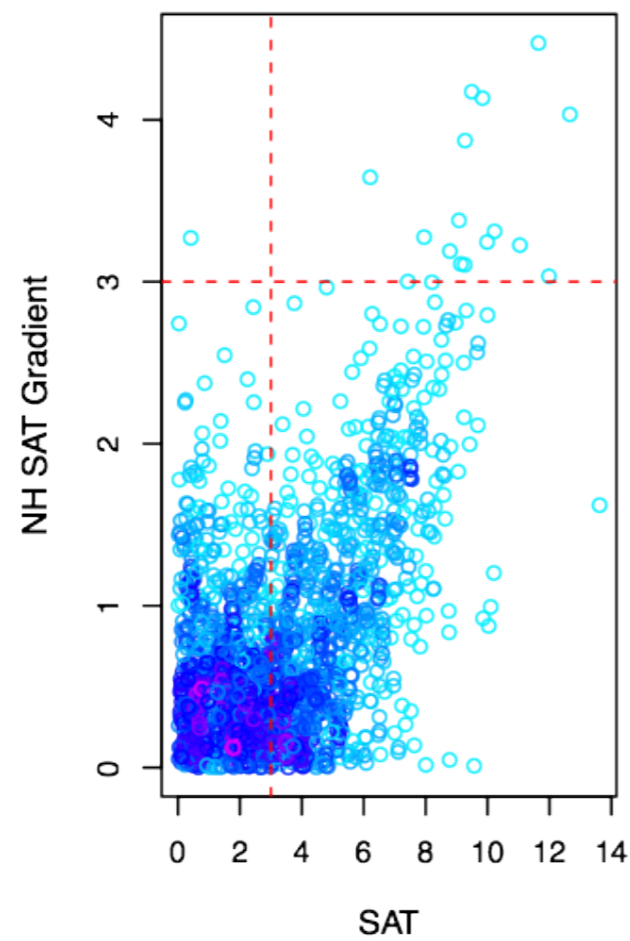

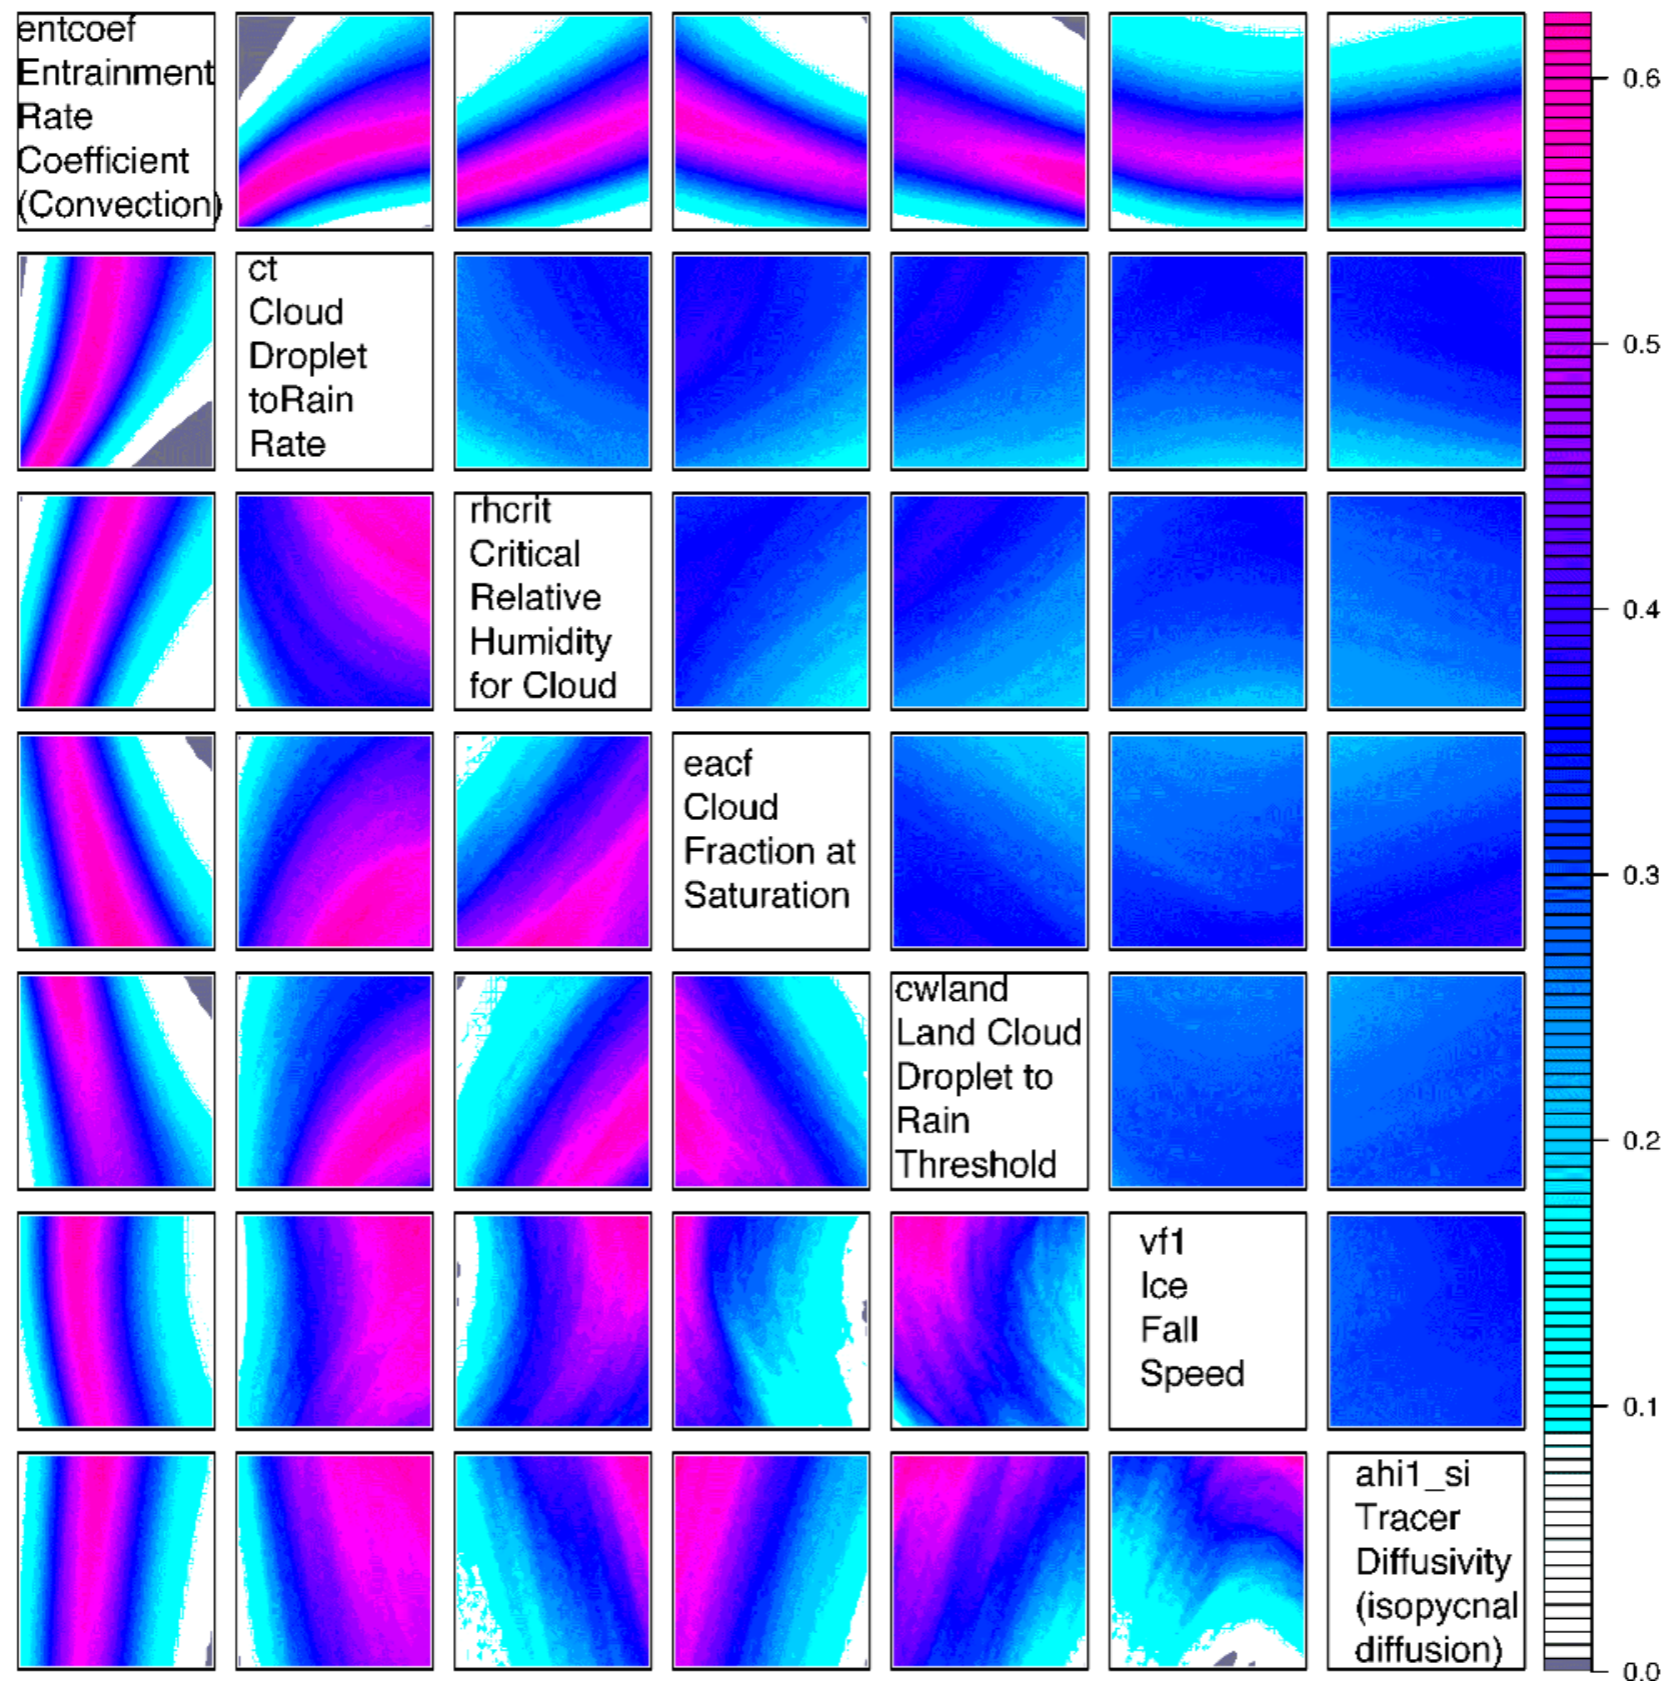

SCYC Validation

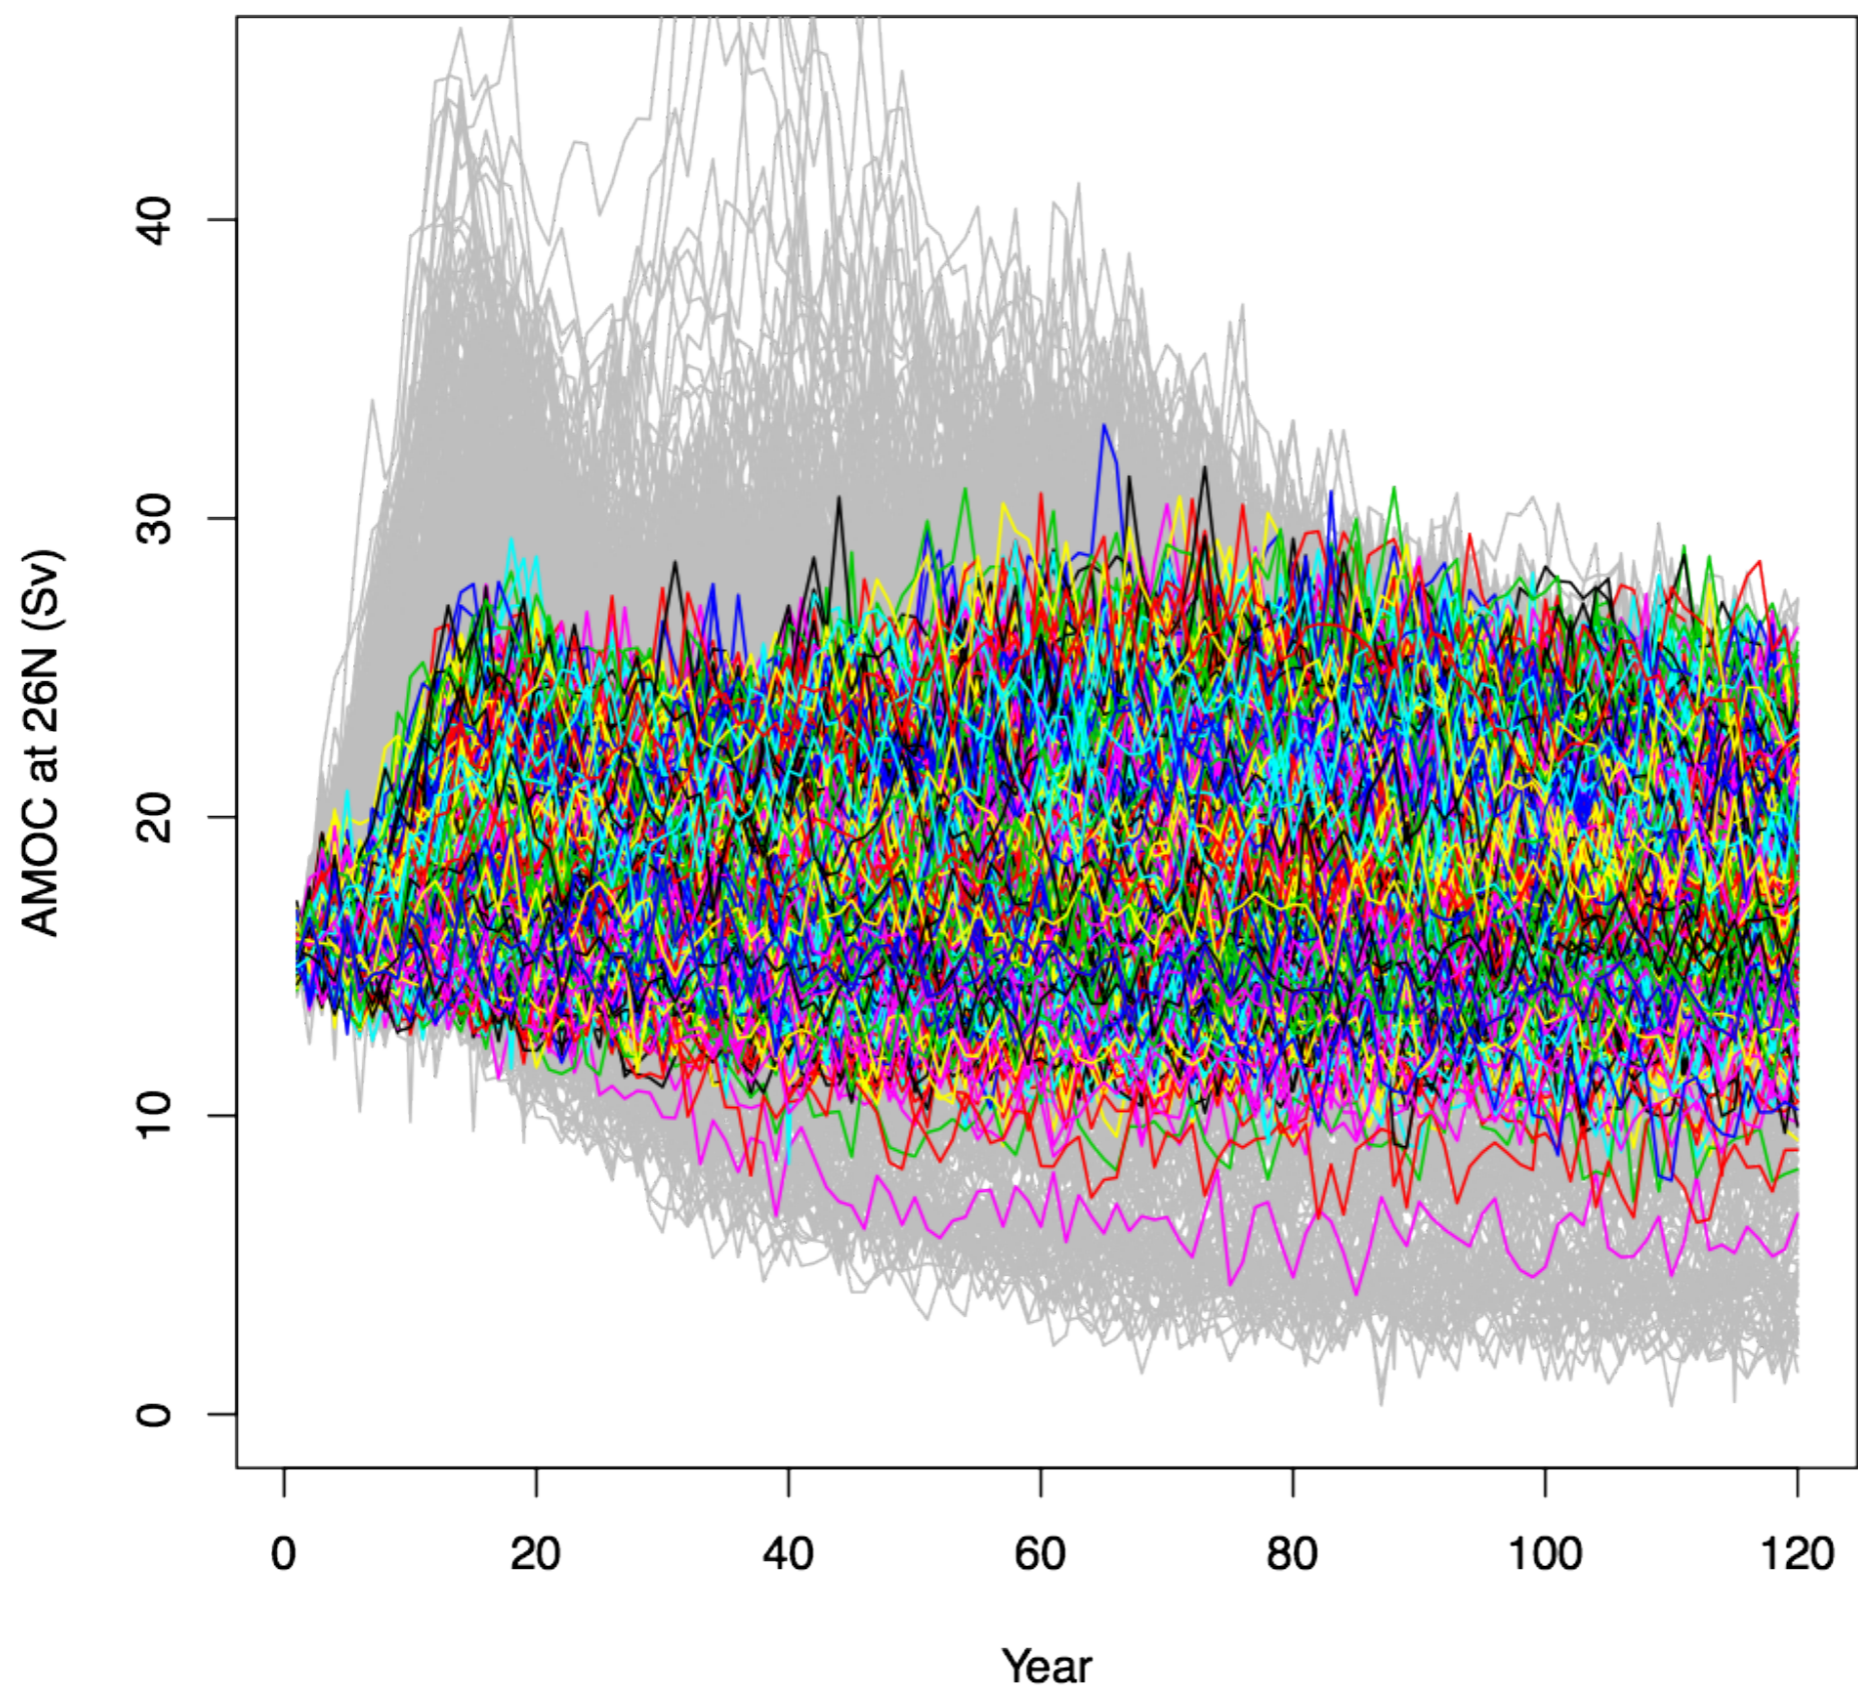

PRECIP Validation

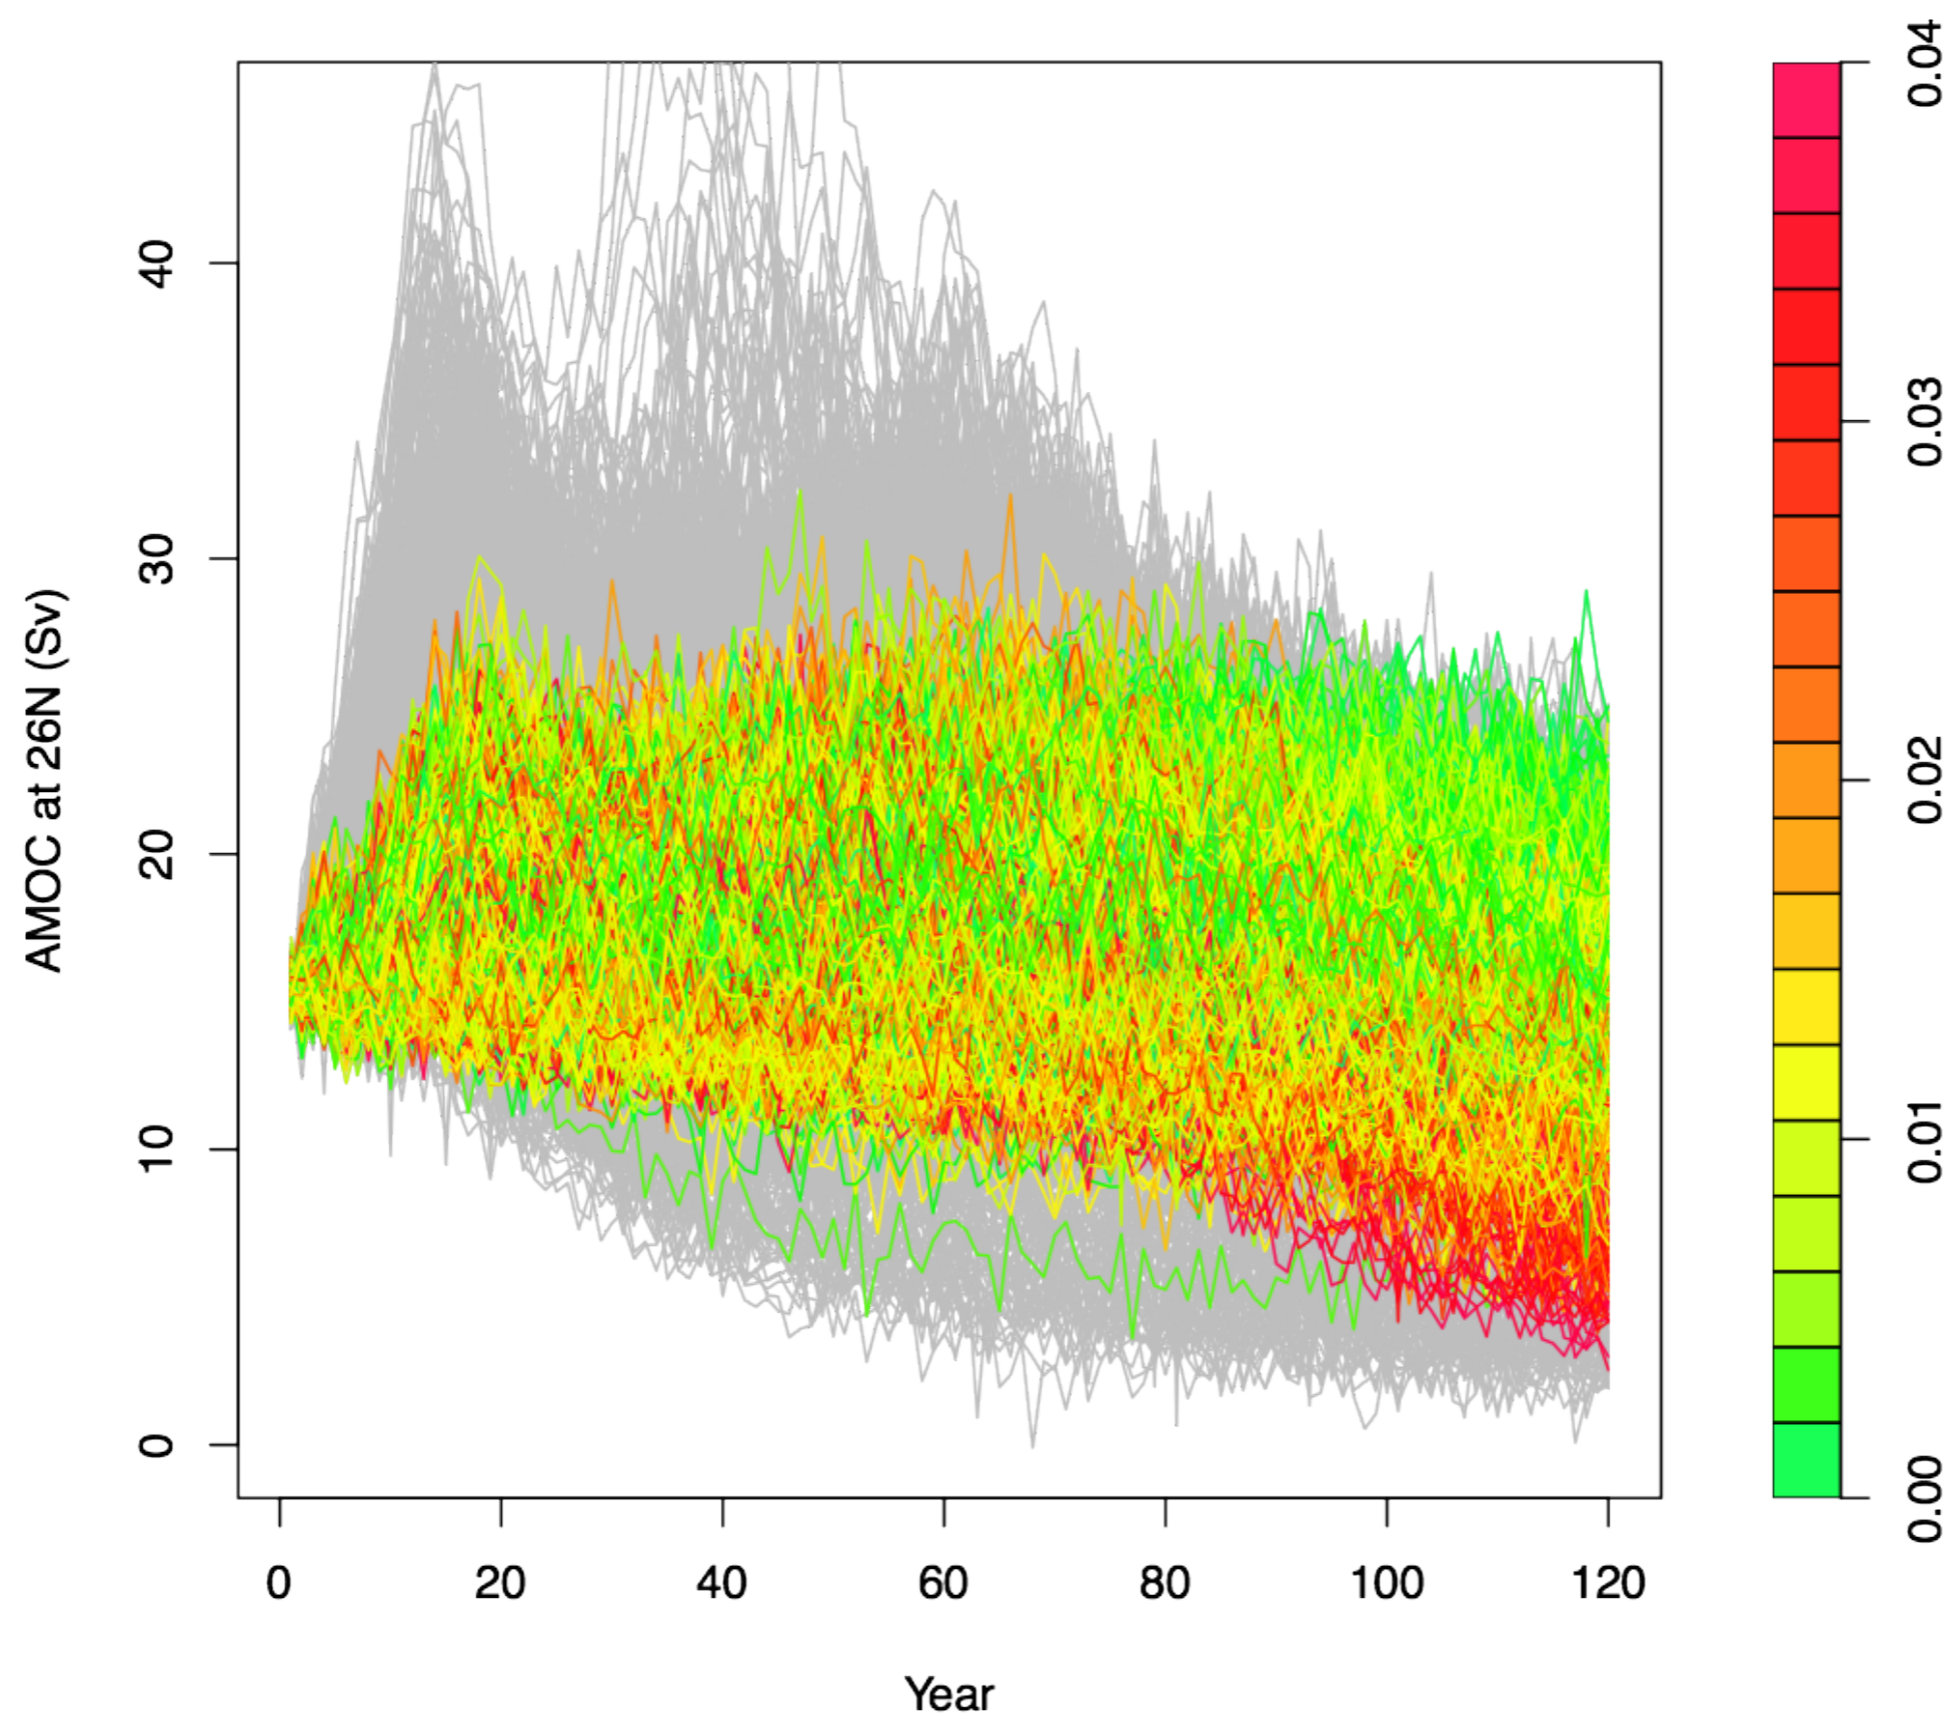

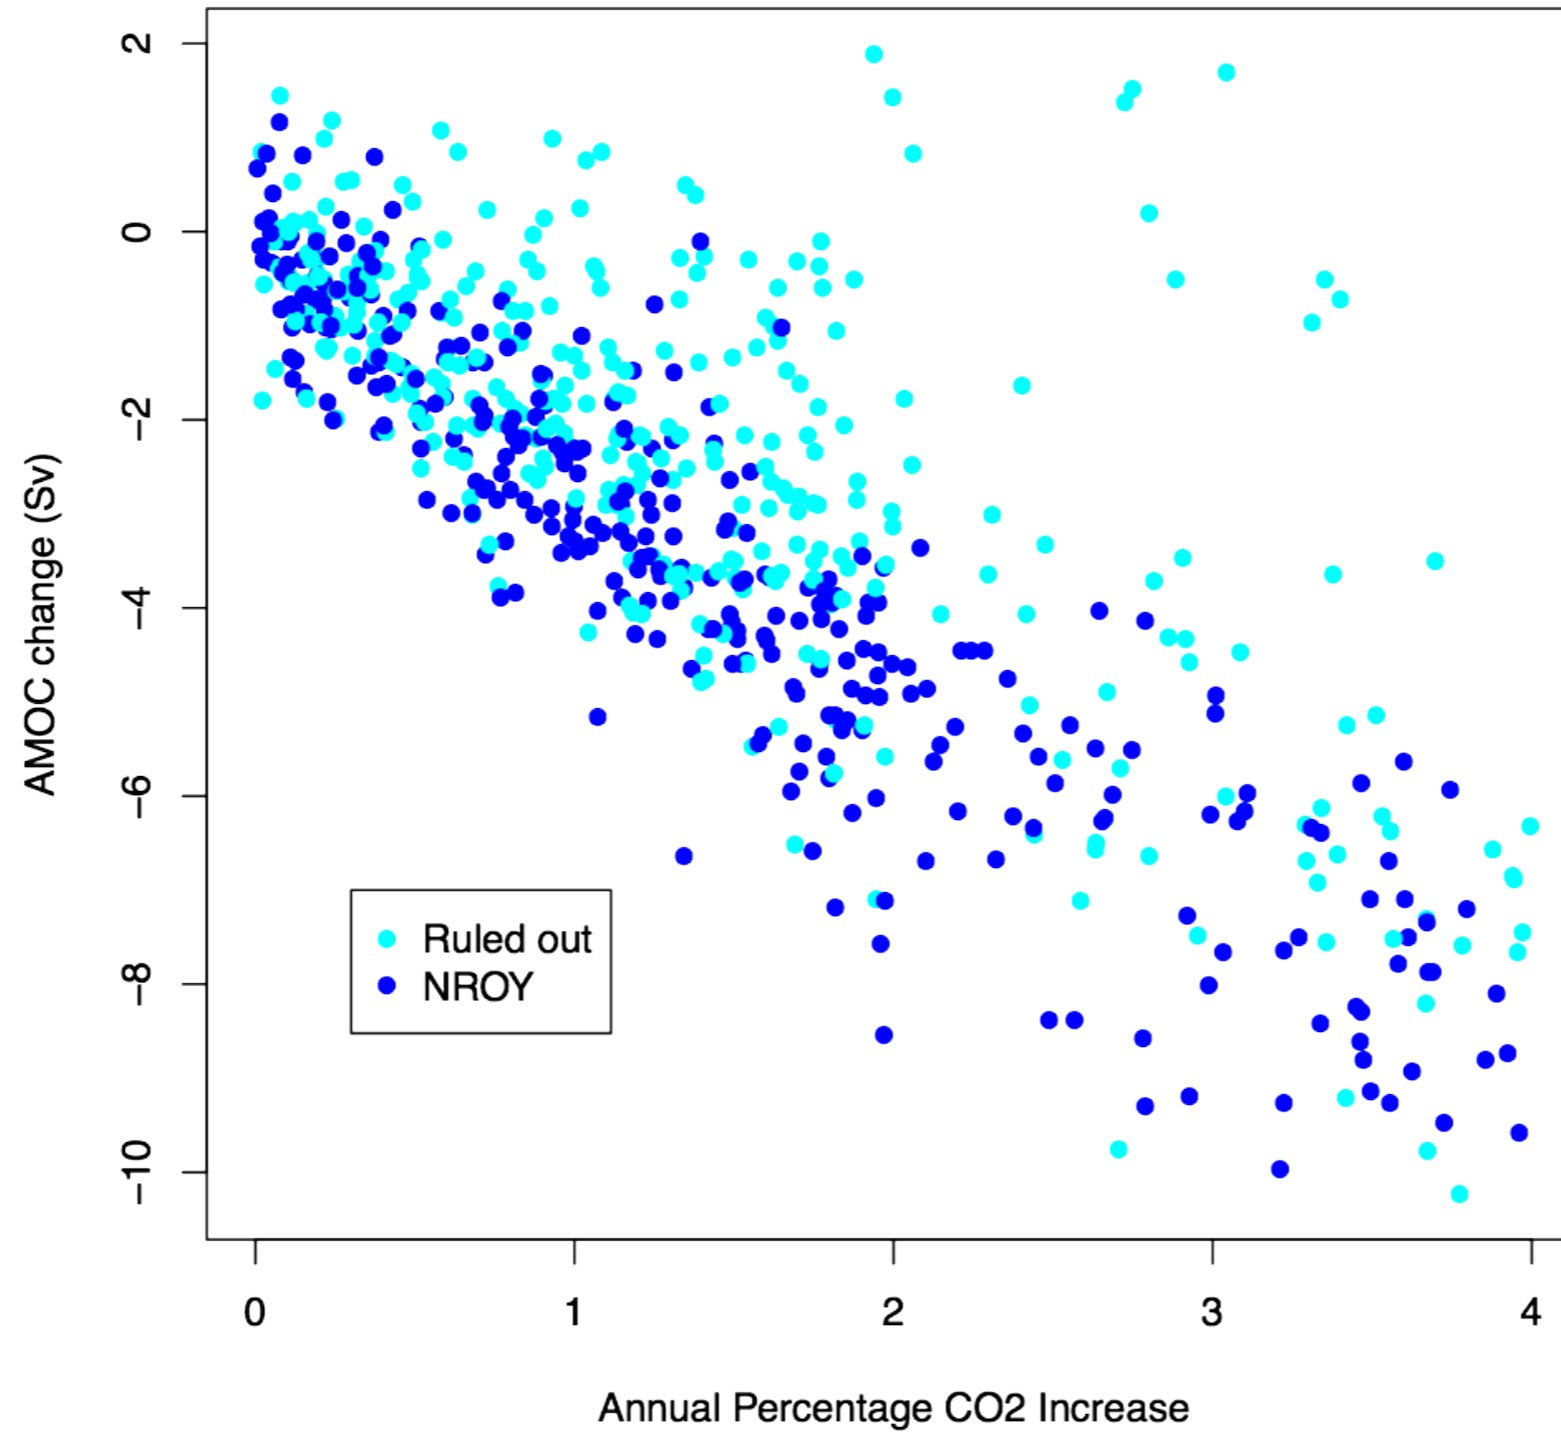

NROY Control AMOC in the RAPIT ensemble

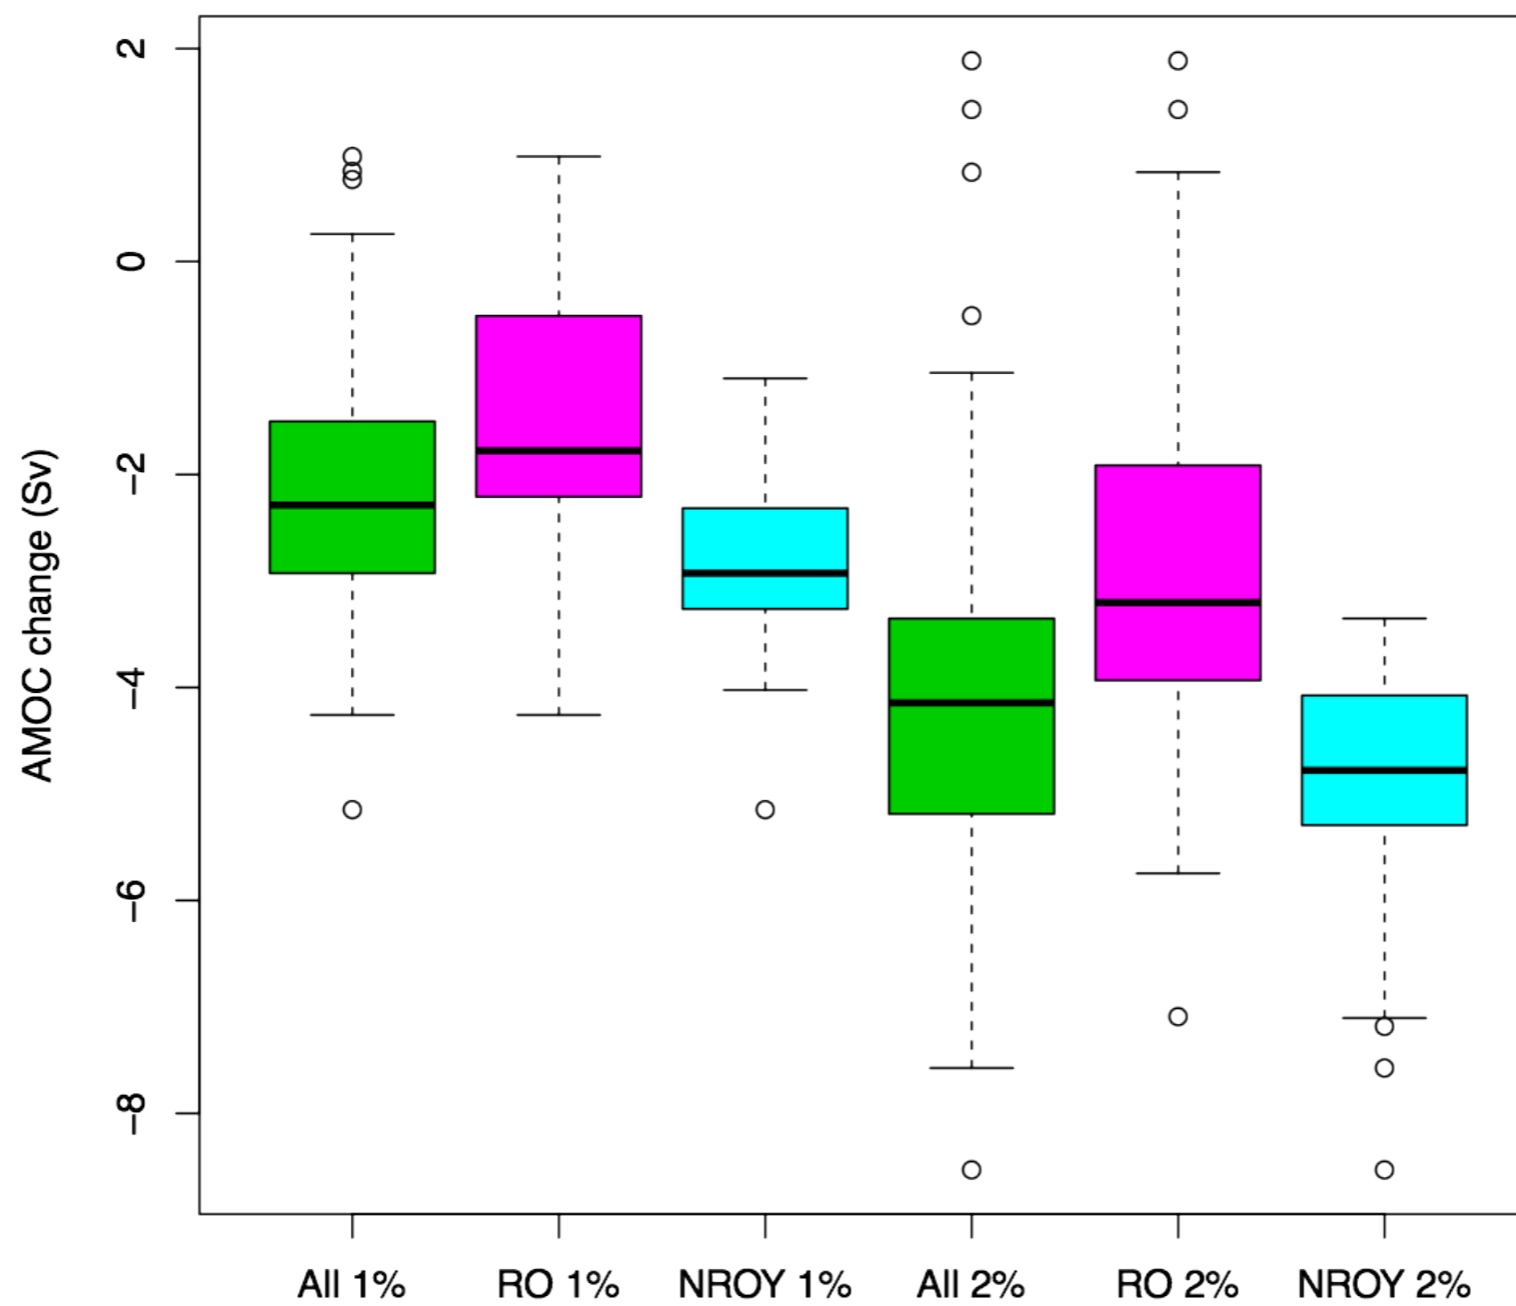

Transient NROY AMOC in the RAPIT ensemble

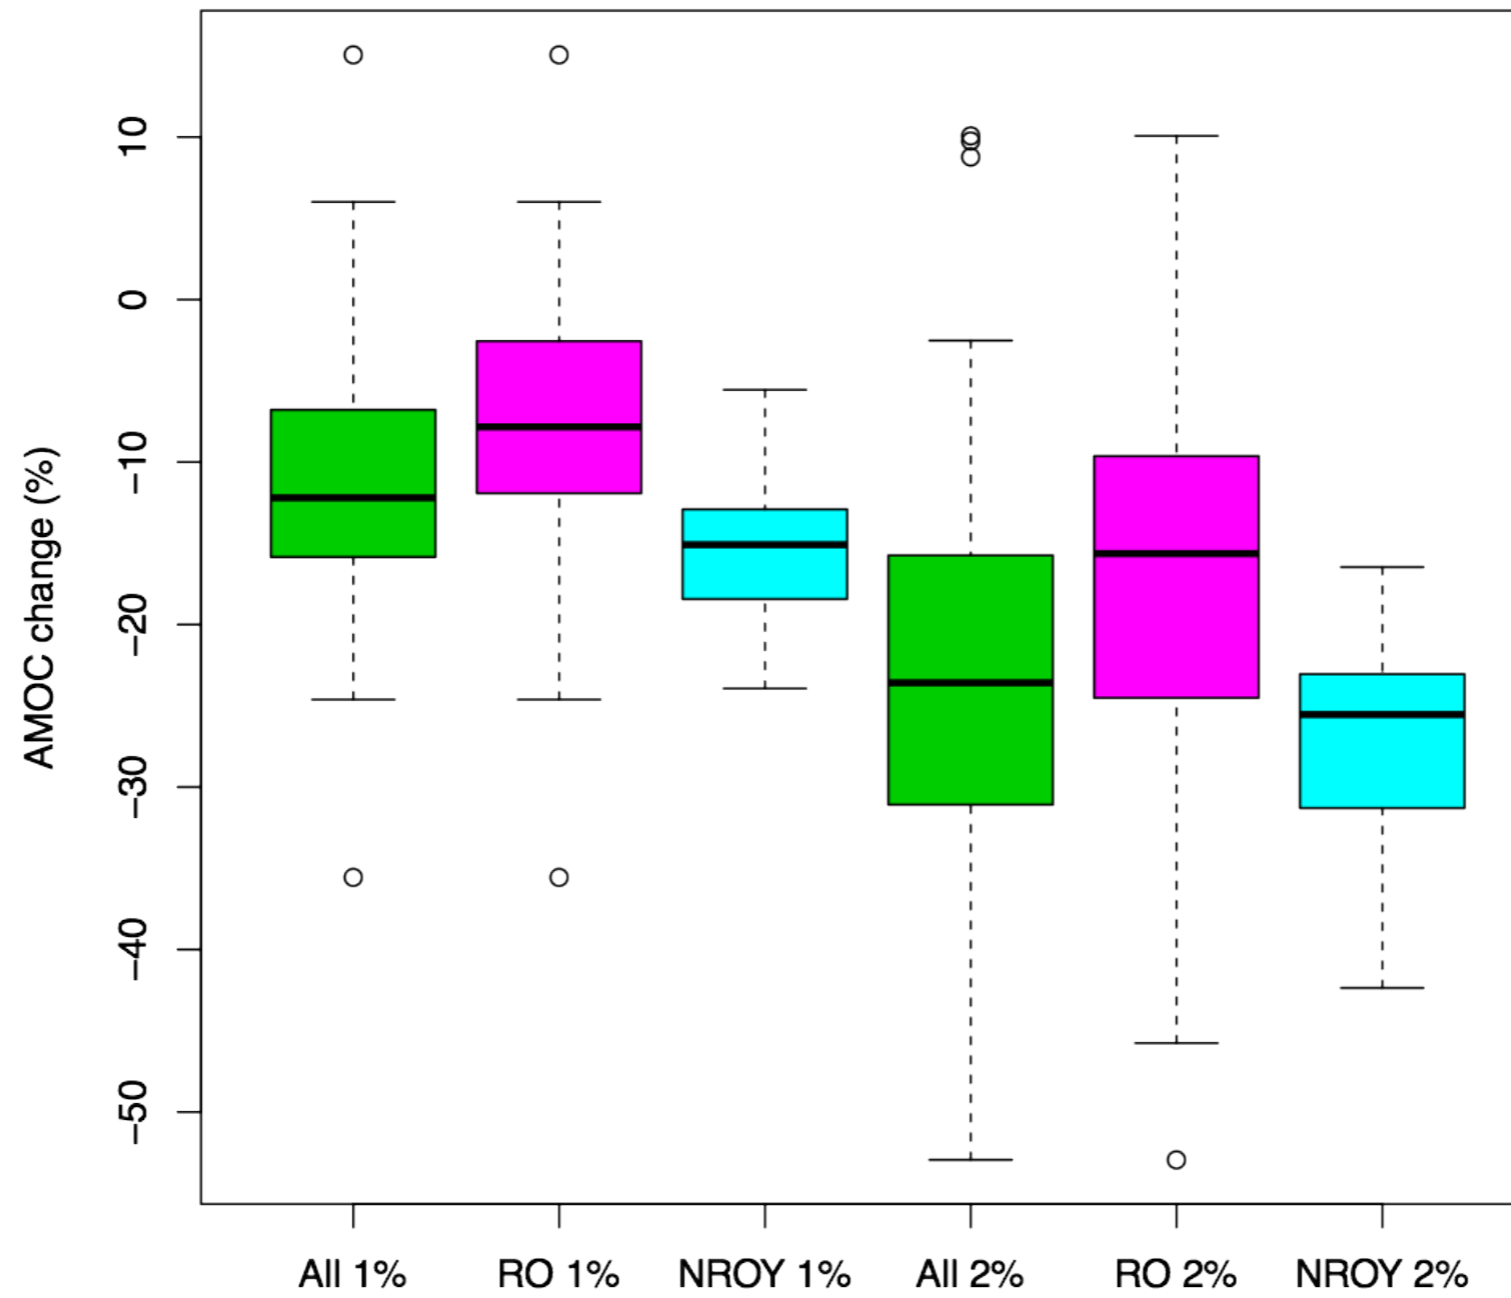

Average AMOC Change over last 20 years

Distribution of AMOC change in response to forcing

Distribution of % AMOC change in response to forcing

Conclusions

- We are building the machinery for risk estimation
- The RAPIT ensemble has more than 4 Million years of HADCM3 output
- Anyone is free to use it
- 20th Century coming soon
