

Sensitivity of Tropical Cyclone Frequency and Intensity to Cumulus Convective Activity in a High Resolution GEOS-5 Model

Young-Kwon Lim and Siegfried D. Schubert

NASA Goddard Space Flight Center

Introduction

- 1. It was found at the last meeting that realistic simulation of the Atlantic tropical storms and hurricanes ($\sim 0.5^\circ$ resolution) was challenging relative to the other regions (e.g., Pacific).**
- 2. Is increased (0.25°) resolution helpful for improving the simulation of the tropical cyclones in terms of storm numbers, intensity, and shape of tropical cyclone (e.g., warm core magnitude and its vertical location, maximum wind, SLP deepening, compactness of TC center, radius of maximum wind, etc.)?**
- 3. Here we will focus on the impact of modifying the cumulus convective activity at 0.25° resolution. In particular we will examine the sensitivity to the minimum entrainment threshold.**

Introduction

- **Determination of Cumulus Entrainment Limit**

$$\mu_m = \alpha/D$$

minimum entrainment rate (μ)

$\alpha = \text{const}$ (positive),

$D = \text{PBL depth} \sim \text{Diameter for the largest convective plume}$

- **Increase in the minimum cumulus entrainment rate (i.e., gradually turning off the cumulus parameterization) in the model to suppress the parameterized deep cumulus convection.**

Experiment and analysis

- 1. Three different minimum entrainment rates (strong, less strong, weak(control, default)) were applied for the active hurricane year (2005) and inactive year (2006).**
- 2. Three member ensembles are conducted for each entrainment experiment, all at the spatial resolution of 0.25 degree.**
- 3. We examine the model's capability for reproducing the hurricane characteristics for two contrasting hurricane years (2005, 2006), with a focus on:**
 - a. the sensitivity of the storm simulation to the change in cumulus entrainment threshold, and**
 - b. how that change influences the atmospheric stability, which will determine the atmospheric circulation structures and TC characteristics**

The number of Atlantic TSs (member mean) wrt. different configuration of convective cloud scale (minimum entrainment rate (**referred to as MER**))

	MER= ($\mu_m=1.0\text{km}^{-1}$)	MER= ($\mu_m=0.7\text{km}^{-1}$)	MER= ($\mu_m=0.4\text{km}^{-1}$)	Obs.
2005	31	24	18	27

How can we explain the increased storm numbers and intensity under suppression of parameterized cumulus convection?

We focus on moist static stability and associated atmospheric features.

Moist Static E. and Vertical change in Theta E

Moist Static Energy

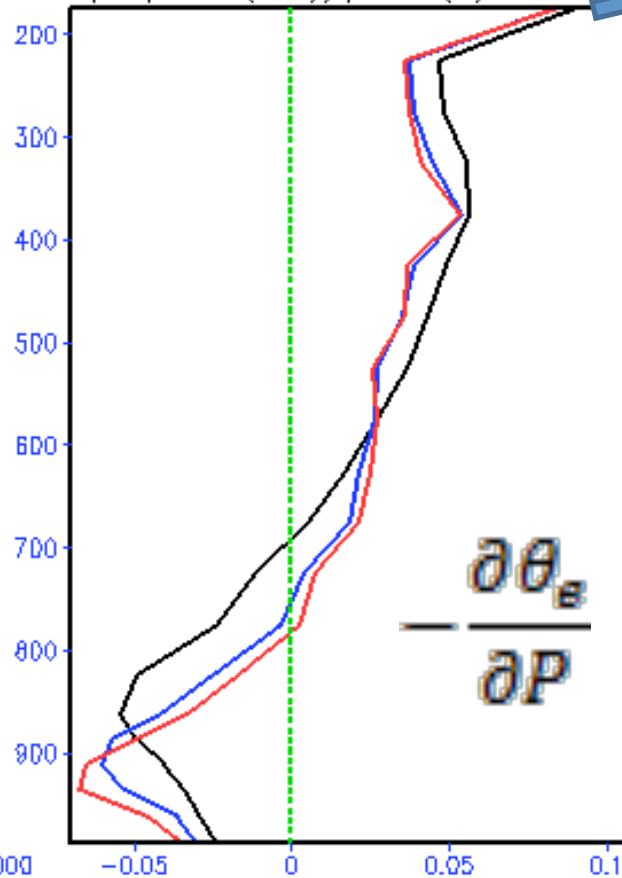

ThetaE ver. grad.

MSE and $-\partial(\text{EPT})/\partial(P)$ over the Atlantic (Jun–Nov)

a) Moist Static Energy (J/kg)

b) $-\partial(\text{EPT})/\partial(P)$

MSE is generally similar to equivalent potential T

Black: (A) Red: (C)
Blue: (B)

Relatively stronger theta_e decrease with height in the strong MER runs -> conditionally more unstable atmosphere

Temperature and Humidity difference profile

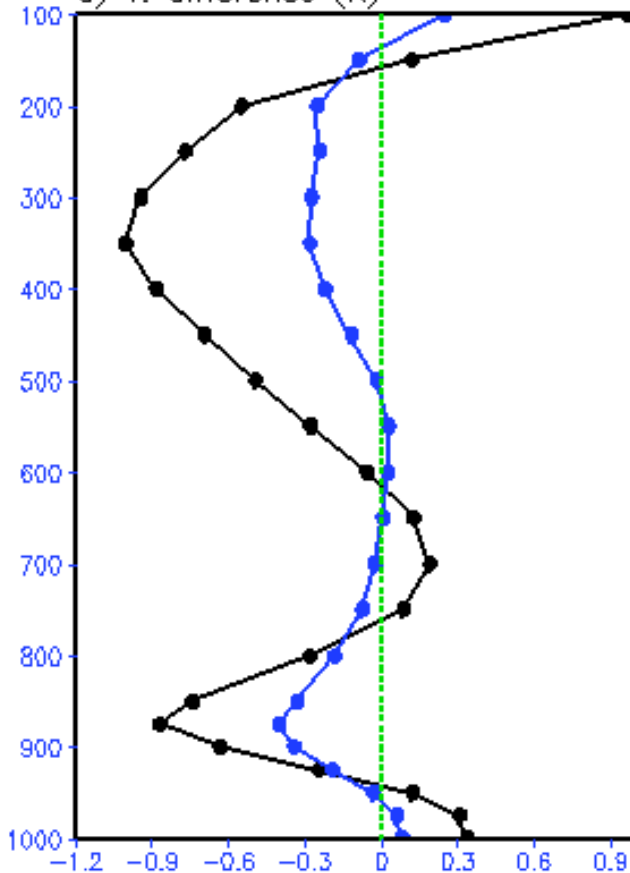

T difference

q difference

Difference in T and humidity over the Atlantic basin (Jun–Nov)

a) T. difference (K)

b) Humidity difference (kg/kg)

**Generally cool T
response to the
strong MER**

Black: (A) – (C)

Blue: (B) – (C)

**Drier at near-surface
-> requires a flux of
water vapor from
the ocean sfc. to the
air (positive LH flux
possible)**

**Moist at lower-level
and dry at upper-
level -> upward
moisture flux
possible**

Latent heat and Evaporative fluxes

LH difference

SH doesn't seem
to contribute to
moist static
instability

What takes place as a result of this atmospheric instability?

(as shown on the next few slides.....)

Strong upward motion, lower-level convergence and positive vorticity, moisture flux convergence, more resolved-scale convective activity --> increased TC numbers and intensity

Vertical motion (OMEGA) and Moisture flux conv.

Vertical Vel. (OMEGA)

Moist. Flux. Conv.

OMEGA and Moisture flux convergence over the Atlantic (Jun–Nov)

a) OMEGA*100

b) Moisture flux conv.

Black: (A) Red: (C)

Blue: (B)

Stronger upward motion with larger MER (unstable condition),

larger lower-level moisture flux convergence (active moist convection possible)

Vorticity (850) and Near sfc. wind var. (10m)

Vorticity

Near sfc. Wind var.

Lower-level (850) vorticity and Near sfc. wind var.(10m) during TC season

a) Vorticity(850)*10⁶ (A)

d) Near sfc. wind var.(10m) (A)

b) Vorticity(850)*10⁶ (C)

Stronger
convergence and
moist
convection**

Conclusion and Discussion

- 1. High-resolution (0.25 degree) with slight increase in MER produced better organized TC structures and more realistic TC numbers and intensity over the Atlantic.**
- 2. Further increase in MER produces even stronger TCs, but tends to overestimate the TC numbers**
- 3. Increase in MER constrains the parameterized deep convective activity (result: increase in large-scale prcp., decrease in convective prcp.). Stronger suppression of the cumulus parameterization constructs more unstable atmosphere (LH flux, lower-level moistening and upper-atmosphere cooling contributes to development of unstable atmosphere).**
- 4. Upward motion and moisture flux convergence is enhanced. It results in more tropical storms and hurricanes. Strong hurricane (category up to 4) is captured.**
