### JOINT U.S. CLIVAR/OCB WORKING GROUP:
Heat and Carbon Uptake by the Southern Ocean

#### Goals:
- Improve understanding of the role of mesoscale eddies in the heat and carbon uptake by the Southern Ocean.
- Improve understanding of how the Southern Ocean stratification, circulation and heat and carbon uptake will respond to a changing climate.

What is the role of the Southern Ocean in the global climate system?

1. It may account for up to half of the annual oceanic uptake of anthropogenic carbon dioxide from the atmosphere (cf., Gruber et al., 2009)

2. Vertical exchange in the Southern Ocean is responsible for supplying nutrients that fertilize three-quarters of the biological production in the global ocean north of 30°S (Sarmiento et al., 2004)

3. It may account for up to 70 ± 30% of the excess heat that is transferred from the atmosphere into the ocean each year (see analysis of IPCC AR4 models)

4. Southern Ocean winds and buoyancy fluxes are the principal source of energy for driving the large scale deep meridional overturning circulation throughout the ocean (e.g., Toggweiler and Samuels, 1998; Marshall and Speer, 2012)
The Antarctic Circumpolar Current system
SOWG Outcomes and Deliverables

- Observationally-based data/model metrics for the consistent evaluation of modeling efforts by Southern Ocean and Antarctic scientists.

- A White Paper, possibly in two parts, for the scientific community and funding agencies that: (i) assesses the state of our understanding of the role of eddies in the Southern Ocean in both the data and the models; and (ii) identifies the most critical observational targets needed to fill in the gaps in our understanding of the role of the Southern Ocean in present and future climate.

- A Workshop/Conference jointly sponsored with the Oceanic Carbon Uptake Working Group, open to Southern Ocean and Antarctic scientists as well as carbon cycle scientists, with the goal of (i) sharing the developed metrics for model evaluations; (ii) identifying important biases in the AR5/CMIP5-type model simulations of present and future climate, stemming from the lack of mesoscale eddies, (iii) providing guidance for estimating and reducing uncertainty in climate projections.

- A summary of WG activities/products for the U.S. CLIVAR and OCB newsletters and websites.
SOWG Planned Activities

- **Spring/Summer 2012** – Bi-monthly teleconferences: progress on development of targets and model assessment
- **Fall 2012** – 1st WG Meeting (coincident with Fall AGU) to: a) discuss/propose potential targeted process or measurement campaigns that will allow alignment of model-derived and observational evidence; and b) discuss/proposal targeted process or sensitivity studies in available models with appropriate tracers and outputs to match our observational colleagues efforts
- **Spring 2012/2013** – Bi-monthly teleconferences: progress on development of measurement campaigns and modeling studies
- **Summer 2013** – Bi-monthly teleconferences: plan and arrange a larger workshop/conference to frame science questions motivated by new measurements, to evaluate the ability of high-resolution models to reproduce these effects, and to foster climate model improvements.
- **2012-2013** – conference calls every 6 months involving co-chairs of this WG (I. Kamenkovich and J. Russell) and the WG on “Oceanic carbon uptake in the CMIP-5 models” (“Carbon Uptake WG”, cochairs: A. Bracco, C. Deutsch and T. Ito), to collaborate on the interpretation of model analysis in the Southern Ocean
- **Fall/Winter 2013** – Monthly teleconferences: write/submit white paper, summarizing key results from WG and workshop/conference.
- **Spring/Summer 2014** – 2nd WG Meeting and workshop/conference, joint with the Carbon Uptake WG, to update wider community on progress
Responsiveness to agency concerns:

This Working Group addresses key concerns of three supporting agencies, in particular:

**NOAA:** Describing and understanding the state of the climate system through integrated observations and analysis. Improving climate predictive capability from weeks to decades.

**NASA:** Understanding how climate variations induce changes in the global ocean circulation; improving predictions of climate variability and change [using satellite observations]; understanding the role of slowly varying components of the earth system (e.g. ocean and ice) in climate.

**NSF:** Advancing discovery, knowledge and understanding in climate science; understanding processes and exploiting new observing techniques; analyzing process studies to address known deficiencies in climate models; identifying critically important questions and the facilities and research required to address them; providing feedback on long-range scientific priorities.
Zonal heat content changes (TJ/m²): CMIP3 models

- Substantial differences between models
- Some models show export of heat from SO into thermocline while other models show cooling at low latitudes
CMIP-5 Earth System models

Zonal integrated carbon uptake: 1995-1870 [kg/m/yr]*10^5
New Tools:

1) Southern Ocean Observations
2) Southern Ocean State Estimate
3) Mesoscale Resolving Models
SOOS Observing System Components

The locations of more than 60,000 Argo profiles of temperature and salinity collected during the 24 months of the IPY. Courtesy of Mathieu Balbeoch, JCOMMOPS.

White circles indicate location of current or planned drill holes through ice shelves, allowing sampling of underlying ocean waters.

Map of proposed moored arrays (red circles) to sample the primary Antarctic Bottom Water formation and export sites.

The ship-of-opportunity lines in the Southern Ocean that contribute to SOOS.

Repeat hydrographic sections to be occupied by SOOS. Symbols indicate the WOCE/CLIVAR designations for each line.

Hydrographic sections (lines) and moorings (circles) occupied as contributions to the IPY SASSI program. Many of these lines are near Antarctic bases and could be repeated more regularly as a contribution to the SOOS.
The Southern Ocean State Estimate (SOSE)

(Nominal Resolution is 1/6°)

**Southern Ocean State Estimation**  
A modern general circulation model, the MITgcm, is least squares fit to all available ocean observations. This is accomplished iteratively through the adjoint method. The result is a physically realistic estimate of the ocean state. SOSE is being produced by Matthew Mazloff as part of the ECCO consortium and funded by the National Science Foundation. Computational resources are provided in part by the NSF TeraGrid. (Nominal Resolution is 1/6°)
